Radiologische follow-up na afronden behandeling bij glioblastoom	952

Startpagina - Gliomen

Waar gaat deze richtlijn over?

De richtlijn is van toepassing op alle volwassen patiënten met een glioom. De richtlijn gaat in op astrocytomen en oligodendrogliomen. Ependymomen, gliomen op ruggenmergniveau en gliomen die vooral op de kinderleeftijd voorkomen, zoals het pilocytair astrocytoom, worden buiten beschouwing gelaten.

De richtlijn gliomen geeft aanbevelingen over diagnostiek, behandeling, nazorg en organisatie van zorg bij patiënten met een (mogelijk) glioom. De richtlijn beoogt hiermee de kwaliteit van de zorgverlening te verbeteren, het klinisch handelen meer te baseren op wetenschappelijk bewijs dan op ervaringen en meningen, de transparantie te vergroten en de diversiteit van handelen door professionals te verminderen.

Voor wie is deze richtlijn bedoeld?

De richtlijn is bestemd voor zorgverleners in de tweede (of derde) lijn die betrokken zijn bij de diagnostiek, behandeling en begeleiding van patiënten met een (verdenking op een) glioom. Deze zorg vereist een multidisciplinaire aanpak waarbij neuroloog, neurochirurg, radioloog, patholoog, radiotherapeut, internist-oncoloog, verpleegkundigen, verpleegkundig specialisten, klinisch neuropsychologen, huisartsen, IKNL-consulenten palliatieve zorg en het palliatief consult team betrokken kunnen zijn.

Voor patiënten

Het grootste deel van de kwaadaardige tumoren die in de hersenen ontstaan zijn tumoren van het steunweefsel. De cellen (de glia-cellen) die het steunweefsel vormen, steunen, voeden, beschermen en isoleren de zenuwcellen. Een tumoren van het glia-weefsel heten gliomen, deze zijn meestal kwaadaardig. Deze richtlijn heeft betrekking op patiënten met gliomen, die in de tweede of derde lijn behandeld worden. De richtlijn richt zich op diagnostiek, behandeling en nazorg. Patiënteninformatie over gliomen is te vinden op de website van Thuisarts via: *[in ontwikkeling]*

Status van de richtlijn

In de laatste herziening (2023) zijn de volgende modules herzien/ontwikkeld:

- Epidemiologie
- Typering/gradering diffuse gliomen
- Beeldvorming ter nadere differentiatie
- Indicatie geriatrisch assessment
- Behandeling van ouderen/kwetsbaren
- Beeldvorming ten behoeve van behandeling

De werkgroep heeft ook bekeken of de overige modules konden worden aangepast aan de laatste WHO-classificatie. Dit is niet haalbaar gebleken omdat de onderliggende literatuur berust op eerdere WHO-classificaties.

Verantwoording

Laatst beoordeeld : 11-07-2023

Laatst geautoriseerd : 11-07-2023

Voor de volledige verantwoording, evidence tabellen en eventuele aanverwante producten raadpleegt u de Richtlijnendatabase.

Epidemiologie

Gliomen zijn een relatief zeldzame vorm van kanker. Jaarlijks krijgen ongeveer 1300 volwassen patiënten in Nederland de diagnose diffuus glioom (grafiek 1), waarvan 1000 bevestigd door weefselonderzoek. De incidentie is al jaren stabiel en ligt gestandaardiseerd voor de Europese bevolking rond 6 per 100.000 inwoners voor tumoren bevestigd door weefselonderzoek, en rond 8 per 100.000 als klinisch verdachte gevallen worden meegerekend. Deze laatste groep betreft patiënten die niet zijn geopereerd, bijvoorbeeld vanwege hun slechte conditie.

Diffuse gliomen komen vaker voor bij mannen (Ostrom, 2022). Hoewel verschillende risicofactoren zijn onderzocht, heeft alleen therapeutische, ioniserende straling een duidelijke etiologische invloed. Vooral degenen die als kind radiotherapie ondergingen, bijvoorbeeld vanwege leukemie, hebben een hogere kans op het ontwikkelen van een glioom (Ohgaki, 2005).

Gliomen worden geclassificeerd volgens de Wereldgezondheidsorganisatie (WHO, 2021), zie tabel 1.

Tabel 1. WHO-classificatie (2021) van diffuse gliomen

WHO-indeling	Type
Graad 1	<i>Pilocytair astrocytoom</i> <i>Astroblastoom, MN1-mutatie</i>
Graad 2	Oligodendroglioom, IDHmut + 1p/19q-codeletie, WHO graad 2 Astrocytoom, IDHmut, WHO graad 2 <i>Pleiomorf xanthoastrocytoom (PXA)</i> <i>Chordoid glioom</i>
Graad 3	Oligodendroglioom, IDHmut + 1p/19q-codeletie, WHO graad 3 Astrocytoom, IDHmut, WHO graad 3 <i>Pleiomorf xanthoastrocytoom (PXA)</i>
Graad 4	Astrocytoom, IDHmut, WHO graad 4 Glioblastoom, IDHwt, WHO graad 4 [¥] Diffuus hemisferisch glioom, H3 G34 mutant* Diffuse midline glioma, H3 K27 mutant

Tabel 1. Hoofdgroepen gliomen. In de WHO classificatie 2021 worden de gliomen onderverdeeld in voorkomend op kinderleeftijd versus volwassen leeftijd. De gliomen van de kinderleeftijd vallen buiten het bestek van deze richtlijn. Cursief gedrukte gliomen zijn circumscrepe astrocytaire gliomen en zijn minder frequent voorkomend dan de diffuse gliomen.

* Zeldzame tumoren die ook op jongvolwassen leeftijd voorkomen.

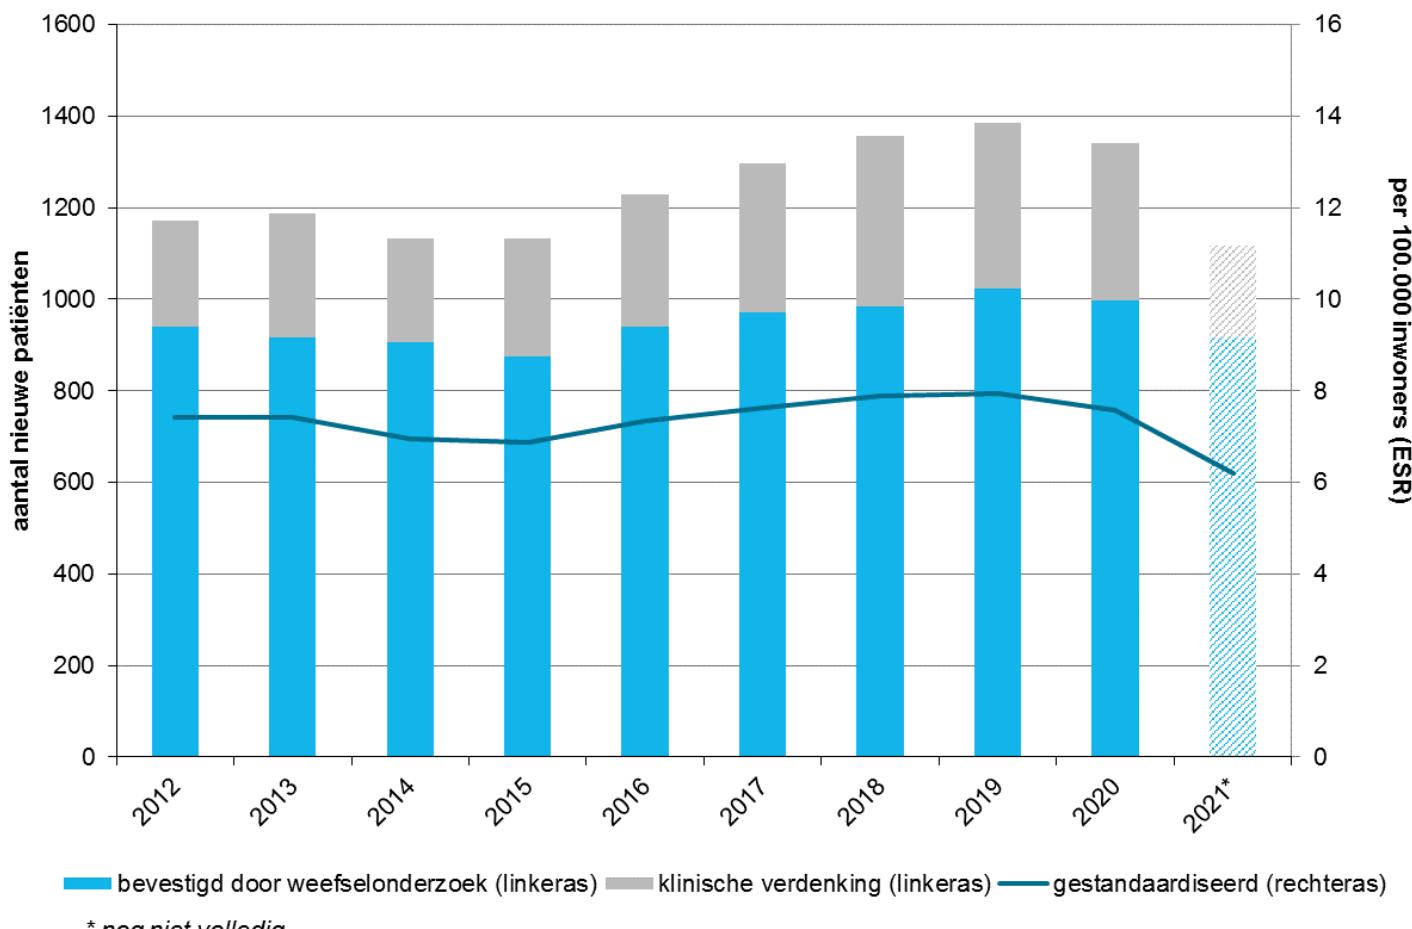

¥ Subtypes: reuscel glioblastoom (kunnen ook IDHmut zijn), gliosarcoom, epithelioid glioblastoom.

Van de door weefselonderzoek bevestigde diffuse gliomen betreft het merendeel (75%) een glioblastoom (grafiek 2).

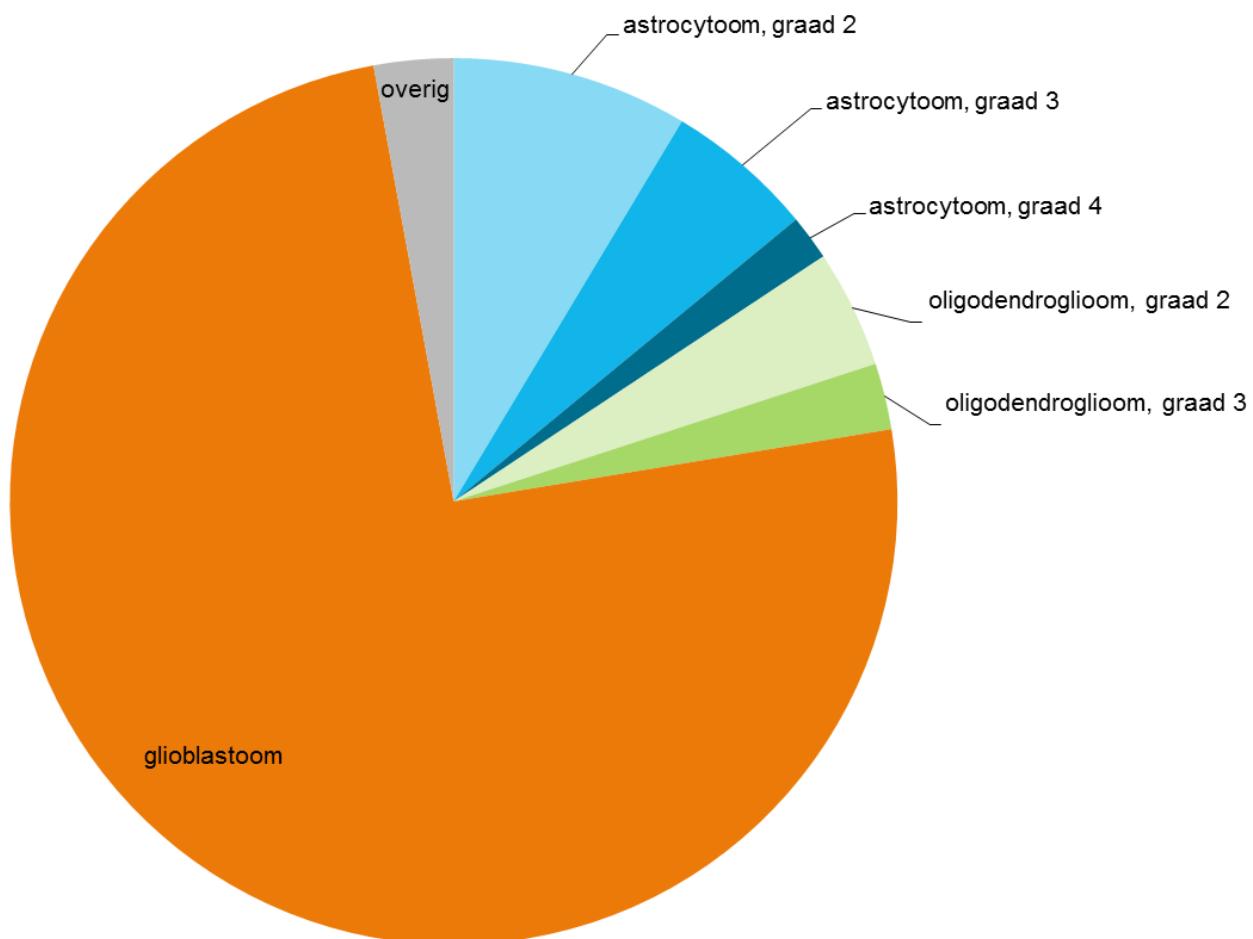

Gliomen groeien vaak uitgebreid in het omliggende hersenweefsel, wat adequate behandeling bemoeilijkt. Metastasering naar andere delen van het lichaam komt vrijwel niet voor. Afhankelijk van het tumortype en de tumorgraad krijgen vrijwel alle patiënten te maken met recidiefgroei na een eerste behandeling.

De overleving van patiënten met een glioom is sterk afhankelijk van de WHO-graad: in de periode 2012–2021 in Nederland was de 1-jaarsoverleving van patiënten met een door weefselonderzoek bevestigd WHO graad 2 glioom 90%, van degenen met een WHO graad 3 glioom 69%, en van degenen met een WHO graad 4 glioom 42% (grafiek 3). De 5-jaarsoverleving van deze patiënten bedroeg respectievelijk 70%, 38% en 5%.

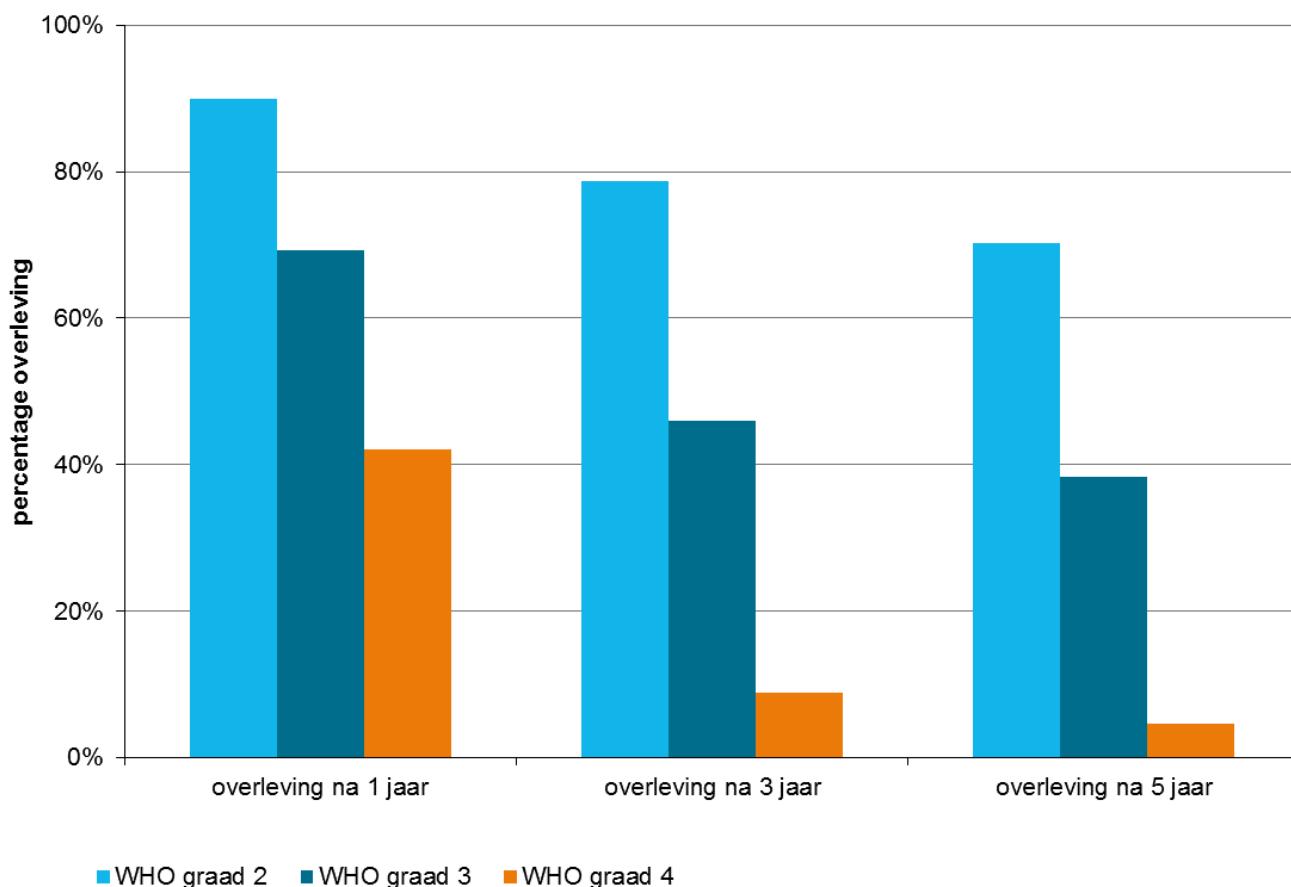

Grafiek 1. Aantal nieuwe gevallen van diffuse gliomen per incidentiejaar (Nederland) in de periode 2012–2021, absoluut (staaf) alsmede gestandaardiseerd voor de leeftijdsopbouw van de Europese bevolking (ESR; lijn)

Grafiek 2. Subtypes diffuse gliomen door weefseldiagnostiek bevestigd in de periode 2012–2021, in Nederland.

Grafiek 3. De 1-, 3-, 5-jaarsoverleving voor de diagnose diffuus glioom per WHO gradering ((WHO graad 2, 3 en 4) in Nederland.

■ WHO graad 2 ■ WHO graad 3 ■ WHO graad 4

Diagnostiek bij Gliomen

Deze module is onderverdeeld in de volgende submodules en sub-submodules:

- Beeldvormende diagnostiek
 - Initiële beeldvorming
 - Aanvullende beeldvorming
- Neuropathologie
 - Typering/gradering diffuse gliomen
 - Moleculaire veranderingen diffuse gliomen

Verantwoording

Beeldvorming ter nadere differentiatie

Uitgangsvraag

Wat is de gewenste beeldvorming bij patiënten met een verdenking glioom ter vaststelling van de diagnose?

Aanbeveling

Overweeg het gebruik van DWI en perfusie MRI voor het onderscheid tussen glioom en lymfoom of hersenmetastase.

Overweeg perfusie MRI voor het onderscheid tussen hoog- en laaggradig glioom.

Overleg bij klinische consequenties en twijfel in een neuro-oncologisch MDO met aanwezigheid van terzake kundig radioloog.

Overwegingen

Voor- en nadelen van de interventie en de kwaliteit van het bewijs

Het doel van deze uitgangsvraag was om de aanvullende waarde van geavanceerde beeldvorming bij patiënten met een verdenking op een glioom (bij wie al iets is gezien op beeldvorming), in vergelijking met alleen conventionele beeldvorming te beoordelen. Er is één systematische review (Dunet, 2016), waarin FET-PET vergeleken werd met FDG-PET. Naast methodologische beperkingen werd de vergelijking niet getrokken met conventionele beeldvorming alleen (indirect bewijs). Bewijskracht voor de kritieke uitkomstmaten was zeer laag. Dit betekent dat andere studies kunnen leiden tot nieuwe inzichten. Er kunnen op basis van enkel de literatuur geen sterke aanbevelingen geformuleerd worden over de aanvullende waarde van geavanceerde beeldvorming vergeleken met conventionele beeldvorming alleen voor patiënten een verdenking op een glioom.

Meest relevante studies ter beschrijving

Diverse systematische/meta-analyses werden niet meegenomen in de literatuursamenvatting omdat deze niet voldeden aan de PICO. Deze studies betroffen over het algemeen onderzoeken waarbij de geavanceerde techniek niet werd vergeleken met conventionele MRI als controle. Daarnaast hadden veel studies een geselecteerde populatie met reeds bevestigd glioom (danwel andere laesie) waarbij retrospectief of in een case-control /two gate design de techniek werd onderzocht. Aangezien de literatuursamenvatting slechts één van de geavanceerde beeldvormende techniek beschrijft, zijn beknopt in tabel 1 en 2 de resultaten van studies naar andere geavanceerde technieken uitgelicht. Voor het onderscheid tussen gliomen en andere laesies (lymfoom, metastasen) zijn perfusie MRI met DSC en ASL, MRS en DTI/DWI onderzocht (tabel 1). Hooggradig glioom en lymfoom werden met hoge sensitiviteit en specificiteit onderscheiden middels DSC (Liang, 2014). Metastase en hooggradig glioom konden eveneens met hoge sensitiviteit en specificiteit van elkaar worden onderscheiden middels perfusie MRI met DSC, ASL of DCE (Suh, 2018), ASL (Fu, 2019) en MRS (Wang, 2017). Zhang et al (2020) rapporteert hoge sensitiviteit en specificiteit in het onderscheiden van glioblastoom, metastase en lymfoom met DWI en DTI. Overigens werd bij deze laatste studie geen referentietechniek gerapporteerd. Mede gezien het gehanteerde studie-design in veel van deze studies dienen deze resultaten met voorzichtigheid te worden geïnterpreteerd.

Ook in het onderscheid tussen hoog- en laaggradige gliomen (tabel 2) wordt er een hoge sensitiviteit en specificiteit gerapporteerd van diverse perfusie MRI technieken en parameters (DSC, ASL, DCE). De gerapporteerde sensitiviteit en specificiteit van MRS is iets lager, hoewel nog steeds >70% (Wang, 2019). Een directe vergelijking tussen perfusie MRI en MRS is in deze studies overigens niet verricht. Ook hier geldt dat de resultaten met voorzichtigheid geïnterpreteerd dienen te worden.

In de studie door Shaw (2019) werd onderzocht of FDG-PET-CT alleen, of in combinatie met MRI kan bijdragen aan het differentiëren tussen hooggradige histologie (WHO IV glioblastoom, WHO III glioom en metastasen) en laaggradige histologie (WHO II glioom en benigne afwijkingen). De studiepopulatie bestond voor een deel uit patiënten die diagnostiek voor verdenking glioom ondergingen en voor een deel uit patiënten met reeds vastgesteld glioom. Vanwege beperkte sensitiviteit en negatief voorspellende waarde, concludeerden de auteurs dat een negatieve FDG-PET-CT alleen of in combinatie met MRI, niet leidend moet zijn in de beslissing voor observatie waar anders chirurgie aanbevolen zou worden.

Tabel 1 Differentiatie gliomen ten opzichte van niet gliomen

Study ID	N studies (totaal patiënten)	Differentieert tussen	Techniek (interventie)	Conventionele beeldvormende techniek (controle)	Techniek (referentie)	Diagnostische accuratessemaat (95% CI)	QUADAS beoordeelbaar

Waarden en voorkeuren van patiënten (en evt. hun naasten/ mantelzorgers)

Geavanceerde MRI-technieken zijn relatief weinig belastend voor de patiënt, aangezien deze over het algemeen worden toegevoegd aan de standaard MRI scan. Een PET-scan is meer belastend, aangezien dit een separaat en – de voorbereidingstijd in ogenschouw nemend – meer langdurig onderzoek is. Daarnaast gaat dit gepaard met (beperkte) stralenbelasting, hetgeen sommige patiënten als meer ingrijpend beschouwen. Niet alle geavanceerde technieken zijn overal allemaal beschikbaar. Het kan zijn dat patiënten wel een bepaalde voorkeur hebben voor een bepaalde techniek. Omdat er geen eenduidig bewijs is dat een specifieke techniek beter is dan een andere, is er geen reden om te denken dat de topografische variatie invloed heeft op de behandeling of uitkomst.

Kosten (middelenbeslag)

Het aantal nieuwe patiënten met een glioom in Nederland bedraagt ±1300 per jaar.

De kosten van geavanceerde MRI zullen over het algemeen met name betrekking hebben op een verlenging van het standaard uitgevoerde MRI-onderzoek. Deze verlenging is relatief beperkt (5-15 min), maar is gezien de schaarste van MRI-capaciteit wel van belang. PET betreft een geheel additioneel onderzoek dat duurder is dan MRI, en waarvoor de tracer (FET) niet standaard overal beschikbaar is. Bij de werkgroep zijn geen studies naar kosteneffectiviteit voor deze geavanceerde technieken bekend.

Aanvaardbaarheid, haalbaarheid en implementatie

DWI en DSC MRI zijn in Nederland breed beschikbaar en geïmplementeerd. De overige geavanceerde MRI-technieken (ASL, DCE, MRS) zijn niet in alle centra beschikbaar. PET is minder toegankelijk en de tracer (FET) is niet standaard overal beschikbaar.

De werkgroep is van mening dat bij klinische consequenties en twijfel de patiënt besproken dient te worden in een neuro-oncologisch multidisciplinair overleg met aanwezigheid van een terzake kundig radioloog. Zie document 'Kwaliteitscriteria neuro-oncologie' (LWNO, 2022 voor de kwaliteitseisen van terzake kundig radioloog.

Rationale van de aanbeveling: weging van argumenten voor en tegen de diagnostische procedure

Er is onvoldoende bewijs dat PET-onderzoek bijdraagt aan de differentiële diagnostiek bij patiënten met een verdenking op glioom. Hierbij is de sensitiviteit van FDG-PET beduidend lager (en onder de norm) dan FET-PET.

De breed beschikbare geavanceerde MRI-technieken DWI en perfusie MRI lijken van waarde bij het differentiëren tussen hooggradig glioom, metastase en lymfoom en voor het onderscheid tussen hoog- en laaggradig glioom, maar bij het ontbreken van goede studies valt niet te zeggen wat de daadwerkelijke diagnostische kracht van deze technieken is. MRS lijkt iets minder goed te zijn voor het onderscheid tussen hoog- en laaggradig glioom.

Onderbouwing

Achtergrond

Nadat er een afwijking in de hersenen is vastgesteld die zou kunnen passen bij een glioom (middels CT dan wel MRI) blijft de diagnose soms onzeker. Belangrijke differentiële diagnosen zijn andere maligne aandoeningen (zoals metastase of lymfoom), demyelinisatie, abces, een infectie anderszins, of vasculaire aandoeningen. Deze vereisen alle een andere behandeling, die soms met spoed moet worden ingezet. Daarnaast is het type en graad van een vermoedelijk glioom van belang. Onzekerheid omtrent de diagnose leidt nu soms tot onnodig of onvolledig operatief ingrijpen en zou kunnen worden voorkomen met betere niet-invasieve, beeldvormende diagnostiek. Het is echter de vraag of en welke aanvullende beeldvormende technieken een toegevoegde waarde hebben boven de conventionele, structurele beeldvorming die routinematig wordt verricht, bestaande uit T2-gewogen (al dan niet met vochtonderdrukking: FLAIR) en pre- en post-contrast T1-gewogen sequenties.

Conclusies

1. Sensitivity (glioma or non-glioma) (critical)

Very low GRADE	<p>It is unclear whether add-on FET-PET is more sensitive compared to add-on FDG-PET in discriminating between glioma and non-glioma lesions in patients suspected of glioma.</p> <p><i>Source: Dunet, 2016</i></p>
---------------------------	---

2. Specificity (glioma or non-glioma) (critical)

Very low GRADE	<p>It is unclear whether add-on FET-PET is more specific compared to add-on FDG-PET in discriminating between glioma and non-glioma lesions in patients suspected of glioma.</p> <p><i>Source: Dunet, 2016</i></p>
---------------------------	--

3. Positive predictive value, negative predictive value (PPV, NPV) (important)

No GRADE	<p>No information was found regarding the effect of initial imaging followed by add-on advanced imaging on positive predictive value or negative predictive value when compared with initial imaging only in patients suspected of glioma.</p> <p><i>Source: -</i></p>
-----------------	--

4. Area under the curve (important) (glioma or non-glioma)

Very low GRADE	<p>It is unclear whether add-on FET-PET had a higher discriminative value compared to add-on FDG-PET in discriminating between glioma and non-glioma lesions in patients suspected of glioma.</p> <p><i>Source: Dunet, 2016</i></p>
-----------------------	---

Effect of initial imaging followed by add-on advanced imaging (any outcome)

No GRADE	<p>No information was found regarding the effect of initial imaging followed by add-on advanced imaging on any outcome when compared with initial imaging only in patients suspected of glioma.</p> <p><i>Source: -</i></p>

Samenvatting literatuur

Description of studies

In the systematic review with meta-analysis by Dunet (2016), five diagnostic accuracy studies were included (190 patients). Eligible studies used both ¹⁸F-fluoro-ethyl-L-tyrosine (FET) positron emission tomography (PET) and ¹⁸F-fluoro-deoxy-glucose (FDG)-PET and compared both with histology (reference). Patients were newly diagnosed with brain lesions or suspected of a recurrent brain tumor and did not undergo treatment before diagnostics. The available data from the five studies were combined in the meta-analysis (n= 119), resulting in a pooled AUC for FDG-PET and for FET-PET separately. Histology was used as a reference, distinguishing between glioma and non-glioma and between low-grade and high-grade glioma. In 3 studies (Floeth, 2006; Lau, 2010; Pichler, 2010), histology as reference standard was not possible in all patients, thus longitudinal observation (clinical follow-up, imaging) was used as reference in some cases. In three studies, not all patients were included in the analysis (Floeth, 2006; Lau, 2010; Pichler, 2010). A more elaborate explanation is provided in the risk of bias tables.

Table 1. Description of included studies in Dunet (2016)

Study	Study characteristics						
	n	Gender (F:M)	Mean age in years (SD)	Patients with a tumor	Diagnostic trajectory	Prevalence of glioma	
Floeth, 2006	14	0:11	54 (12)	4	Contrast enhanced MRI à FET-PET and FDG-PET à histology (biopsies or clinical follow-up)	4/14 (29%)	
Pauleit, 2009	52	16:36	46 (14)	45	MRI à FET-PET and FDG-PET à histology (biopsy)	43/52 (83%)	
Lau, 2010	21	5:13	42 (16)	12	Contrast enhanced MRI à FET-PET and FDG-PET à histology (surgical or clinical/imaging course)	10/21 (48%)	
Plotkin, 2010	15	9:6	44 (11)	15	MRI à FET-PET and FDG-PET à histology (surgical)	15/15 (100%)	
Pichler, 2010	88	NR	NR	14	MRI à FET-PET and FDG-PET à histology (surgical) or longitudinal observation	10/88 (11%)	

Abbreviations: ¹⁸F-fluoro-deoxy-glucose; FDG, ¹⁸F-fluoro-ethyl-L-tyrosine; FET, NR; not reported

Results

1. Sensitivity (glioma or non-glioma) (critical)

For the sensitivity of FET-PET in discriminating between glioma and non-glioma lesions, data from four studies (Floeth, 2006; Pauleit, 2009; Lau, 2010 and Pichler, 2010) could be combined in meta-analysis. Pooled sensitivity was 0.92 (95% CI 0.75 to 0.98). For sensitivity of FDG-PET, pooling the same studies led to a sensitivity of 0.35 (95% CI 0.11 to 0.71).

2. Specificity (glioma or non-glioma) (critical)

For the specificity of FET-PET in discrimination between glioma and non-glioma lesions, data from four studies (Floeth, 2006; Pauleit, 2009; Lau, 2010 and Pichler, 2010) could be combined in meta-analysis. Pooled specificity was 0.62 (95% CI 0.43 to 0.79). For specificity of FDG-PET, pooling the same studies led to a specificity of 0.65 (95% CI 0.48 to 0.79).

3. Positive predictive value, negative predictive value (PPV, NPV) (important)

Neither positive predictive value nor negative value were reported.

4. Area under the curve (important) (glioma or non-glioma)

Data from all five studies could be combined in the meta-analysis for a pooled AUC. The AUC for FET-PET in discriminating between glioma and non-glioma lesions was 0.76 (95% CI 0.67 to 0.84) and for FDG-PET 0.49 (95% CI 0.40 to 0.58).

Level of evidence of the literature

1. Sensitivity (glioma or non-glioma) (critical)

The level of evidence regarding the outcome measure sensitivity was downgraded by three levels because not all study participants were included in the analyses and inclusion of participants with a confirmed diagnosis of a brain tumor or suspected recurrence of a known low-grade glioma (Plotkin, 2010) (-2 risk of bias) and conflicting results within studies for FDG-PET compared with histology (-1, inconsistency).

2. Specificity (glioma or non-glioma) (critical)

The level of evidence regarding the outcome measure specificity was downgraded by two levels because not all study participants were included in the analyses and inclusion of participants with a diagnosis of a brain tumor or suspected recurrence of a known low-grade glioma (Plotkin, 2010) (-2, risk of bias); and two additional advanced imaging techniques were compared (-1, indirectness).

3. Positive predictive value, negative predictive value (PPV, NPV) (important)

The level of evidence regarding the outcome measure PPV and NPV could not be graded.

4. Area under the curve (important) (glioma or non-glioma)

The level of evidence regarding the outcome measure AUC was downgraded by three levels because not all study participants were included in the analyses and inclusion of participants with a diagnosis of a brain tumor or suspected recurrence of a known low-grade glioma (Plotkin, 2010) (-2, risk of bias); two additional advanced imaging techniques were compared (-1, indirectness).

Zoeken en selecteren

A systematic review of the literature was performed to answer the following question: is initial imaging followed by advanced imaging recommended versus initial imaging or additionally imaging techniques only in patients suspected of glioma?

Patients: Patients suspected of glioma in whom a lesion has been seen with imaging (CT or conventional MRI)

Intervention: Initial imaging followed by advanced imaging technique¹

Comparator: Initial imaging (CT, conventional MRI, structural MRI, pre- and post-contrast, T1w, T2w and/or FLAIR)

Reference: Clinical course, histopathology

Outcomes: Diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value, Area Under the Curve (AUC))

Timing and setting: Outpatient clinic (neurology/neurosurgery/oncology)

Timing: Advanced imaging after initial imaging (term: <4 weeks)

Relevant outcome measures

The guideline development group considered sensitivity and specificity as a critical outcome measure for decision making; and negative predictive value, positive predictive value and AUC as important outcome measures for decision making.

A priori, the working group did not define the outcome measures listed above but used the definitions used in the studies.

The working group defined minimal clinically (patient) important thresholds for accuracy measures as $\geq 70\%$

Search and select (Methods)

The databases Medline (via OVID) and Embase (via Embase.com) were searched with relevant search terms from 2014 until January 24th, 2022. The detailed search strategy is depicted under the tab Methods. The systematic literature search resulted in 248 hits. Studies were selected based on the following criteria:

- Systematic review (searched in at least two databases, and detailed search strategy, risk of bias assessment and results of individual studies available) or observational study;
- Full-text English language publication;
- Studies according to PICO.

A total of 29 studies were initially selected based on title and abstract screening. After reading the full text, 28 studies were excluded (see the table with reasons for exclusion under the tab Methods), and one studies was included (Dunet, 2016).

Results

One study was included in the analysis of the literature (Dunet, 2016). Important study characteristics and results are summarized in table 1 and the evidence tables. The assessment of the risk of bias is summarized in the risk of bias tables.

Beeldvorming ten behoeve van chirurgie/radiotherapie

Uitgangsvraag

Wat is de plaats van nieuwe radiologische technieken bij patiënten met een glioom t.b.v. planning van chirurgie/radiotherapie?

Aanbeveling

Overweeg het gebruik van neuronavigatie tijdens resectie van een glioom.

Overweeg bij (verdenking op) een glioom in of nabij eloquente gebieden functie localiserende beeldvorming te gebruiken zoals DTI en/of fMRI voorafgaand aan de resectie.

Overweeg voor het identificeren van de meer maligne tumorcomponenten gebruik te maken van aanvullende beeldvorming zoals PET, perfusie MRI (ASL, DSC, DCE) of MRS.

Overweeg voor een (supra)maximale resectie de infiltratie beter af te beelden door bijvoorbeeld PET, perfusie MRI, MRS of intra-operatieve echografie.

Overwegingen

Voor- en nadelen van de interventie en de kwaliteit van het bewijs

Het doel van deze uitgangsvraag was om te achterhalen wat de waarde van geavanceerde beeldvorming (DTI, fMRI, MRS, CEST, ASL DSC, DCE, MRS, intra-operatieve echografie, neuronavigatie, PET) is bij het plannen van de lokale behandeling bij patiënten met een verdenking op een glioom, in vergelijking met conventionele beeldvorming. Er is voor neurochirurgie één gerandomiseerde trial beschreven (Willems, 2006), waarin resectie met neuronavigatie vergeleken werd met resectie zonder neuronavigatie. Naast methodologische beperkingen was de studiepopulatie zeer klein en divers (zowel glioblastoom als metastase). Bewijskracht voor de kritieke uitkomstmaten was zeer laag. Dit betekent dat andere studies kunnen leiden tot nieuwe inzichten. Er kunnen op basis van enkel de literatuurgeen sterke aanbevelingen geformuleerd worden over de waarde van geavanceerde beeldvorming vergeleken met conventionele beeldvorming voor lokale behandeling van patiënten een verdenking op een glioom.

Ondanks de uitkomst van deze underpowered RCT is neuronavigatie voor vermoedelijke glioom chirurgie wereldwijd als standaard geaccepteerd en wordt deze techniek ook wereldwijd toegepast. De werkgroep is niet bekend met eventuele lopende studies naar deze techniek. In alle Nederlandse klinieken wordt neuronavigatie toegepast en door vele neurochirurgen als effectief en veilig ervaren voor gliomchirurgie.

Voor andere geavanceerde beeldvormende technieken (PET, DTI, fMRI, MRS, CEST, ASL DSC, DCE, intra-operatieve echografie) werden geen artikelen gevonden die aan de PICO voldeden. Wel zijn er twee systematische reviews over dit onderwerp gepubliceerd, alle in het kader van het plannen van een operatie. Caras et al (2020) includeerden uit 435 geïdentificeerde artikelen drie studies over DTI, vijf studies over fMRI en 21 over intra-operatieve MRI. Intra-operatieve MRI wordt in deze richtlijn buiten beschouwing gelaten, omdat deze faciliteit niet in Nederland beschikbaar is noch verwacht te zullen komen. Geen van deze studies

betrof een RCT. Hoewel patiënten met deze geavanceerde technieken vaker een totale resectie en minder permanente neurologische uitval leken te hebben, was er geen statistisch significant verschil in vergelijking met neuronavigatie. In een Cochrane review (Barone, 2016) werden vier RCT's geïncludeerd met elk een andere geavanceerde beeldvormende techniek: intra-operatieve MRI, 5-ALA fluorescentie, neuronavigatie (de hierboven beschreven RCT van Willem et al 2006), DTI. Alle studies hadden een groot risico op bias, metname de DTI-studie. Vanwege de grote heterogeniteit was een meta-analyse niet mogelijk. Ook in deze review was er in de individuele studies een grotere mate van resectie met geavanceerde beeldvorming (behoudens neuronavigatie), maar de bewijskracht was zeer laag. Er was geen bewijs voor verbeterde overleving. Op basis van de beschikbare literatuur is er geen bewijs dat het al dan niet toepassen van een van deze beeldvormende technieken zou leiden tot een verandering van operatierisico. Desalniettemin acht de werkgroep het verstandig om bij (verdenking op) een glioom in of nabij eloquente gebieden functie localiserende beeldvorming te gebruiken zoals DTI of fMRI als extra informatie tijdens de resectie. Het kan daarnaast verstandig zijn om voor het identificeren van de meer maligne tumorcomponenten gebruik te maken van aanvullende beeldvorming zoals PET, perfusie (ASL, DSC, DCE) of MRS. De werkgroep is eveneens van mening dat het verstandig kan zijn voor een (supra)maximale resectie de infiltratie beter af te beelden door bijvoorbeeld PET, MRS of intra-operatieve echografie. Eenduidig bewijs voor een individuele aanvullende vorm van beeldvorming naast conventionele MRI ontbreekt echter. Over het gebruik van geavanceerde beeldvormende technieken ten behoeve van het bepalen van het doelgebied voor bestraling is geen afdoende literatuur beschikbaar en acht de werkgroep dat er hiervoor geen indicatie is.

Waarden en voorkeuren van patiënten (en evt. hun naasten/ mantelzorgers)

Veel patienten zullen het advies van het neurochirurgisch en radiotherapeutisch team volgen, dat ingevuld wordt naar overtuiging, lokale beschikbaarheid en middelen. Neuronavigatie, DTI en intraoperatieve echografie lijken niet extra belastend voor de patiënt. Het uitvoeren van CEST, fMRI en ASL neemt meer tijd in beslag, maar wordt door de werkgroep als vergelijkbaar belastend voor de patiënt ingeschat. PET (-CT) wordt door de werkgroep ingeschat als zijnde extra belastend.

Een deel van deze beeldvorming kan bijdragen aan het localiseren van functionele structuren (DTI, fMRI), een ander deel kan bijdragen aan het localiseren van de meest maligne tumorcomponenten (PET, CEST, perfusie, MRS) of aan het localiseren van de infiltratieve tumorzone (MRS, intraoperatieve echografie). Deze technieken zijn niet overal beschikbaar en worden niet altijd toegepast, zonder dat dit betekent dat de kwaliteit van de behandeling hiermee verminderd.

Kosten (middelenbeslag)

Naar inschatting van de werkgroep gaan kosten gepaard met pre-therapeutische MRI-scan met apparatuur. Het is onduidelijk of onder de streep een van de technieken leidt tot hogere danwel lagere kosten.

Aanvaardbaarheid, haalbaarheid en implementatie

DSC-MRI, intra-operatieve echografie en neuronavigatie zijn alle breed beschikbaar, aanvaardbaar en haalbaar. MRI-beeldvorming met ASL, CEST, fMRI, DTI, DCE en MRS behoren niet tot de diagnostische standaard, en zijn niet overal geïmplementeerd in de MRI protocollen. Wel zijn ASL, fMRI, DTI, DCE en MRS

in de academische centra beschikbaar. CEST bevindt zich nog overwegend in het onderzoeksdomain, maar is potentieel wel implementeerbaar op bestaande MRI-scanners. PET, en met name met aminozuur tracers, is daarnaast niet overal beschikbaar.

Onderbouwing

Achtergrond

Momenteel wordt neurochirurgische en radiotherapeutische behandeling van een (verdenking op) glioom gebaseerd op structurele, conventionele beeldvorming met MRI, bestaande uit pre- en post-contrast T1-gewogen beelden en T2-gewogen (al dan niet met vochtonderdrukking: FLAIR) beelden. Het is bekend dat de afwijkingen die hiermee zichtbaar worden gemaakt niet volledig overeenkomen met de microscopische tumoruitbreiding, noch met de meest agressieve delen van de tumor. Daarnaast verschaffen structurele, conventionele MRI-beelden geen informatie over functionele hersengebieden, noch over het verloop van essentiële witte stofbanen. Ten derde is het de vraag of beeldvorming tijdens een operatie de resectie kan ondersteunen en daarmee de uitkomst voor de patiënt kan verbeteren.

Met meer geavanceerde beeldvormende technieken kan meer informatie worden verkregen over tumoruitbreiding en functioneel relevante hersenstructuren. Het is echter de vraag of deze daadwerkelijk kunnen of zouden moeten worden ingezet voor het plannen van behandeling, zoals het bepalen van de uitgebreidheid van operatie in relatie tot eloquente hersengebieden, het identificeren van het optimale target voor een biopsie, of het bepalen van doelgebied van bestraling.

Conclusies

1. Overall survival (critical)

No GRADE	No sufficient information was found regarding the effect of an advanced imaging technique on overall survival when compared with non-neuronavigation surgery in patients suspected of glioblastoma for whom a treatment is planned. <i>Source:</i> -
----------	---

2. Extent of resection (critical)

Very low GRADE	The evidence is very uncertain about the effect of neuronavigation on extent of resection when compared with standard surgery in patients suspected of glioblastoma in whom gross total resection is planned. <i>Source:</i> Willems (2006)
----------------	--

3. Quality of life (critical)

Very low GRADE	The evidence is very uncertain about the effect of neuronavigation on quality of life when compared with standard surgery in patients suspected of glioblastoma in whom gross total resection is planned. <i>Source:</i> Willems (2006)
----------------	--

4. Progression free survival and (intracranial) response (important)

No GRADE	No information was found regarding the effect of an advanced imaging technique on progression free survival and (intracranial) response when compared with using only conventional imaging in patients suspected of glioblastoma for whom a treatment is planned. <i>Source:</i> -
----------	---

5. Neurological/cognitive deterioration (important)

Very low GRADE	The evidence is very uncertain about the effect of neuronavigation on neurological/cognitive deterioration when compared with non-neuronavigation surgery in patients <i>suspected</i> of glioblastoma in whom gross total resection is planned. <i>Source:</i> Willems (2006)
----------------	---

6. PET, DTI, fMRI, MRS, CEST, ASL DSC, DCE, intra-operative ultrasound

No GRADE	No information was found regarding the effect of advanced imaging techniques on any outcome when compared with conventional, structural MRI in patients suspected of glioma for whom a local treatment (surgery/radiotherapy) is planned. <i>Source:</i> -

Samenvatting literatuur

Description of study

In the RCT by Willems (2006), 45 participants were randomly assigned to either surgery involving neuronavigation ($n= 23$) or 'standard' surgery ($n= 22$), between 11-1999 and 12-2002. Patients with a solitary intracerebral space-occupying lesion with (partial) contrast enhancement, eligible for surgical debulking with intention of gross-total resection were included. Patients who already received surgical treatment, or with other known primary tumors elsewhere in the body, were excluded. All included participants were preoperatively evaluated using 0.5T MRI. In participants assigned to surgery involving neuronavigation, a surgical plan was made by localizing the fiducial markers, determination of surgical trajectories and segmentation of the tumor boundaries on the MR image. Neuronavigational equipment could include (when applicable) an infrared pointer device and a mechanically tracked operating microscope with heads-up display. In participants assigned to 'standard' surgery, no use was made of the MR images during surgery. Final diagnosis in patients receiving 'standard' and neuronavigation surgery was glioblastoma in 16 respectively 15, anaplastic glioma in 5 respectively 3, and metastasis in 1 respectively 5. No subgroup analyses by diagnosis were performed. Relevant outcome measures included extent of resection, (subjective) cognitive deterioration and quality of life.

Table 1. Description of included studies

Studie	Intervention		Comparator		Follow-up	Outcomes
	Characteristics	Interventie type/ dose	Characteristics	Type of usual care		
Willem's (2006)	Arm 1 (n= 23) <u>Mean age (SD):</u> 60.6 (12.1) <u>Female:</u> 74% <u>Mean total tumor volume in cm³ (SD):</u> 54.2 (31.4) <u>Mean KPS (SD):</u> 77.4 (19.4) Median KPS: 80 (IQR not reported)	Surgery involving neuronavigation	Arm 2 (n= 22) <u>Mean age (SD):</u> 60.8 (12.1) <u>Female:</u> 64% <u>Mean total tumor volume in cm³ (SD):</u> 68.4 (48.9) <u>Mean KPS (SD):</u> 78.6 (15.5) Median KPS: 80 (IQR not reported)	Standard surgery	72-hours postoperative (extent of resection) 3-month postoperative ((subjective) neurological/cognitive deterioration, quality of life)	Extent of resection (%), (subjective) cognitive deterioration (EORTC QLQ-C30 (cognitive functioning subscale)), quality of life (EORTC QLQ-C30 (global health status))

Abbreviations: EORTC QLQ-C30; European organization for Research and Treatment of Cancer quality of life questionnaire C30

Results

Since no dispersion measures were reported, bar graphs for all outcomes were analyzed using the web-application WebPlotDigitizer.

Surgery with neuronavigation versus conventional MRI without neuronavigation

1. Overall survival (critical)

Median survival time was 5.6 months for participants in the group assigned to surgery involving neuronavigation, and 9 months for participants in the group assigned to 'standard' surgery. The corresponding hazard ratio was 1.6, however measures of dispersion were not reported.

2. Extent of resection (critical)

Willem's (2006) reported on extent of resection using a bar graph showing the change between preoperative and 72-hours postoperative tumor volumes (range 0%-100%). In the group assigned to surgery involving neuronavigation (n= 15), a mean of 13.6% (SD 27.7) of the preoperative tumor volume was left. In the 'standard' surgery group (n= 18), a mean of 28.7% (SD 63.5) of the preoperative tumor volume was left. The mean difference between these residual volumes was -15.10 (95% CI -47.61 to 17.41). This difference was not clinically relevant.

3. Quality of life (QoL) (critical)

Willems (2006) measured quality of life using the EORTC QLQ C30, reported as the difference between pre-operative and 3-months' post-operative QoL. Results for global health status were extracted for the purpose of this chapter (range 0-100, higher scores indicating a higher quality of life). In the group assigned to surgery with neuronavigation (n=8), the mean difference score was 4.8 (SD 24.7). In the 'standard' surgery group (n=11), the mean difference score was 8.5 (SD 53.7). The mean difference between the groups was -3.7 (95% CI -39.76 to 32.36). This difference was not clinically relevant.

4. Progression free survival and (intracranial) response (important)

These outcomes were not assessed in the study by Willems (2006).

5. Neurological/cognitive deterioration (important)

Willems (2006) measured subjective cognitive status with the European organization for Research and Treatment of Cancer quality of life questionnaire (EORTC QLQ C30) cognitive subscale (range 0-100, higher scores indicating a higher level of cognitive functioning), reported as the difference between pre-operative and 3-months' post-operative cognitive status. In the group assigned to surgery with neuronavigation (n=8), the mean difference score was 3.9 (SD 27.3). In the 'standard' surgery group (n=11), the mean difference score was 5.6 (SD 45.9). The mean difference between the groups was -1.70 (95% CI -34.77 to 31.37). This difference was not clinically relevant.

In the group assigned to surgery involving neuronavigation, 4 participants (18.2%) exhibited new or worsened neurological deficits, compared with 10 participants (45%) in the 'standard surgery' group. This resulted in an RR of 0.38 (95% CI 0.14 to 1.04). In 1 participant in the neuronavigation surgery group, and in 8 participants in the 'standard surgery' group, these deficits subsequently subsided either completely or partially. It is not reported how neurological deficits were defined in the study.

Level of evidence of the literature

1. Overall survival (critical)

The level of evidence regarding the outcome measure overall survival was not assessed due to lack of measures of dispersion.

2. Extent of resection (critical)

The level of evidence regarding the outcome measure extent of resection started as high as it was based on an RCT and was downgraded by three levels to very low because lack of blinding, incomplete outcome data (Willems, 2006) (-2 risk of bias), and confidence interval includes both harm and benefit (-1 imprecision).

3. Quality of life (critical)

The level of evidence regarding the outcome measure quality of life started as high as it was based on an RCT and was downgraded by three levels to very low because lack of blinding, incomplete outcome data (Willems, 2006) (-2 risk of bias), and confidence interval includes both harm and benefit (-1 imprecision).

4. Progression free survival and (intracranial) response (important)

The level of evidence regarding the outcome measures progression free survival and (intracranial) response was not assessed.

5. Neurological/cognitive deterioration (important)

The level of evidence regarding the outcome measure neurological/cognitive deterioration started as high as it was based on an RCT and was downgraded by three levels to very low because lack of blinding, incomplete outcome data (Willems, 2006) (-2 risk of bias), and confidence interval includes both harm and benefit (-1 imprecision).

Zoeken en selecteren

A systematic review of the literature was performed to answer the following question: What is the effectiveness of advanced imaging for the benefit of treatment planning (radiotherapy, neurosurgery), compared to conventional MRI in patients with glioma?

Patients: Patients with glioma or suspected of glioma for whom a treatment is planned

Intervention: Advanced imaging technique^[1]: PET, DTI, fMRI, MRS, CEST, ASL DSC, DCE, intraoperative ultrasound, neuronavigation

Comparitor: Conventional MRI, structural MRI

Outcomes: Overall survival, progression free survival, (intracranial) response, neurological/cognitive deterioration, extent of resection, quality of life

[1] DTI = diffusion tensor imaging; PET = positron emission tomography; fMRI = functional MRI; MRS = MR spectroscopy; CEST = chemical exchange saturation transfer; ASL = arterial spin labeling; DSC = dynamic susceptibility contrast; DCE = dynamic contrast enhanced.

Relevant outcome measures

The guideline development group considered overall survival, extent of resection and quality of life as a critical outcome measure for decision making; and progression free survival and neurological/cognitive deterioration as important outcome measures for decision making.

The working group defined the following minimal clinically (patient) important differences:

Survival (progression-free, or overall): hazard ratio < 0.7

Intracranial response: 0.5 SD

Extent of resection: 0.5 SD

Neurological/cognitive deterioration: EORTC cognitive functioning subscale ≥10 points

Quality of life: The minimum important difference (MID) has been estimated to be a difference of 0.08 or more points for the EQ-5D utility index, seven or more points for the EQ-5D VAS (Pickard, 2007), or EORTC global health status subscale ≥10 points

In all other cases, the working group defined the GRADE-standard limit of 25% difference for dichotomous outcomes ($RR < 0.8$ or > 1.25), and 0.5 SD for continuous outcomes as a minimal clinically (patient) important difference.

Search and select (Methods)

The databases Medline (via OVID) and Embase (via Embase.com) were searched with relevant search terms from 2014 until January 24th, 2022. The detailed search strategy is depicted under the tab Methods. The systematic literature search resulted in 248 hits. Studies were selected based on the following criteria:

- Systematic review (searched in at least two databases, and detailed search strategy, risk of bias assessment and results of individual studies available), randomized controlled trial or observational study comparing advanced imaging technique (PET, DTI, fMRI, MRS, CEST, ASL DSC, DCE, intra-operative ultrasound) with conventional MRI/structural MRI);
- Full-text English language publication;
- Studies according to PICO.

A total of 29 studies were initially selected based on title and abstract screening. After reading the full text, 28 studies were excluded (see the table with reasons for exclusion under the tab Methods), and one study was included (Willems, 2006). One systematic review matched the predefined PICO (Barbosa, 2014). This review reported on six studies including Willems (2006), however only the randomized controlled trial by Willems et al. (2006) matched the predefined PICO.

Results

One study was included in the analysis of the literature (Willems, 2006). Important study characteristics and results are summarized in table 1 and the evidence tables. The assessment of the risk of bias is summarized in the risk of bias tables.

Typering/gradering diffuse gliomen

Uitgangsvraag

Op welke wijze dient typering/gradering van diffuse gliomen plaats te vinden?

Aanbeveling

Typeren en graderen van gliomen dient te worden gedaan conform de meest recente WHO-classificatie.

Bepaal de mutatiestatus van IDH bij alle gliomen. Bij patiënten van 55 jaar of jonger met negatieve immuunhistochemie dient dit gevolgd te worden door sequencing voor IDH1 en 2 mutaties.

Onderzoek bij alle gliomen met IDH-mutatie de aan- of afwezigheid van 1p/19q-codeleties. Dit dient onderzoek van de hele arm 1p en 19q te betreffen. Indien verlies van ATRX-expressie of een ATRX-mutatie is aangetoond kan dit achterwege blijven.*

Verricht uitgebreide moleculaire karakterisering bij twijfel over de diagnose en verdenking op een glioom.

Onderzoek op de aanwezigheid van H3F3-K27-mutatie bij patiënten met een glioom in de midline, met name in de thalamus, hersenstam, cerebellum of ruggenmerg.

Bepaal tenminste de MGMT-methyleringsstatus bij oudere patiënten en/of patiënten met een slechte conditie met een glioblastoom (zie module Behandeling ouderen/kwetsbaren).

Overwegingen

In de in 2016 uitgebrachte, gereviseerde WHO-uitgave 'WHO Classification of Tumors of The Central Nervous System' is een belangrijke verandering aangebracht in de definitie van de verschillende tumoren (Louis, 2016). Waar in voorgaande edities de definities van de representanten van de diffuus infiltrerende gliomen steeds gebaseerd waren op morfologische aspecten, zijn deze sinds de editie van 2016 bepaald door discriminerende genetische mutaties die constant voorkomen en prognostische waarde vertegenwoordigen. Dit betreft mutaties van het isocitraat-dehydrogenase-gen (IDH-mutant) en het gecombineerde verlies van de chromosoomarmen 1p en 19q (1p/19q-codeletie). IDH-mutatie (IDHmut) is een prognostisch gunstig teken bij astrocytaire tumoren en is diagnostisch voor de zogeheten IDHmut-astrocytomen (Wick, 2009; Eckel-Passow, 2015; Louis, 2016). Codeletie van 1p/19q tezamen met een IDH-mutatie is diagnostisch voor een oligodendroglioom (Cairncross, 2013; van den Bent, 2015; Louis, 2016). Ook voor zeldzaam voorkomende tumoren is de genetische handtekening definiërend geworden. Subsets van tumoren zoals het bij kinderen voorkomend 'diffuse midline glioma' met een H3F3AK27M-mutatie gelden als een aparte diagnose.¹ Het voorkomen van de H3K27M-mutatie zonder de klinische context van een tumor op een midlinelocatie is echter onvoldoende om de diagnose te stellen (Louis, 2016; Meyronet, 2017; Louis, 2018).

¹Het gaat om mutaties positie K27 van de histon-coderende genen H3F3A, HIT1H3B of HIST1H3C. De mutatie H3F3A (kortweg H3.3 K27M) komt echter het meest voor en is als zodanig opgenomen in de WHO).

Ook voor de gliomen uit de 'circumscripte' groep (pilocytair astrocytoom, ganglioglioom) hebben moleculaire karakteristieken een belangrijke klinische betekenis verworven. Het pilocytair astrocytoom wordt genetisch gekenmerkt door mutaties in de genen geassocieerd met mitogen-activated proteïne kinase (MAPK), in het bijzonder het BRAF-gen. Afgezien van relevantie voor tumorclassificatie zijn bepaalde mutaties ook geassocieerd met de tumormaligniteitsgraad. Zo zijn mutaties in astrocytaire IDH-wildtype (wt) tumoren van TERT, PTEN of EGFR indicatief voor de diagnose glioblastoom.

In 2021 werd een herziene editie van de WHO-classificatie uitgebracht, waarin nieuwe inzichten in tumornomenclatuur en gradering worden geïntroduceerd, en er een nog grotere rol voor moleculaire diagnostiek is weggelegd. Het is belangrijk zich te realiseren dat de diagnostiek op basis van de thans in de classificatie opgenomen mutaties op DNA-niveau een 'moving target' is. Het is goed mogelijk dat toekomstige classificaties niet alleen andere mutaties zullen includeren, maar ook zullen worden uitgebreid met karakteristieke expressiepatronen op RNA- en eiwitniveau en vooral op basis van verschillen in methyleringsprofiel.

De transitie van de voorgaande WHO-edities naar de edities uit 2016 en 2021 waarin genetische definities worden gehanteerd, is gecompliceerd. De problemen die zich kunnen voordoen zijn:
De aansluiting van de oude op de nieuwe terminologie; in het verleden op morfologie / immunohistochemie gebaseerde diagnoses kunnen op basis van huidig moleculaire diagnostiek veranderen. Zo is de diagnose oligoastrocytoom in essentie verdwenen.

In de herziene editie van de WHO-classificatie van hersentumoren wordt de term 'NOS' (not otherwise specified) en 'NEC' (not elsewhere classified) toegepast. Indien moleculair onderzoek niet is verricht (om welke reden dan ook) of indien het technisch niet mogelijk was, zou 'niet anders omschreven' (NOS) moeten worden toegevoegd aan de diagnose, bijvoorbeeld: astrocytoom, WHO graad 2, NOS. Indien moleculair onderzoek wel is verricht en valide resultaten opleverde, maar er geen diagnose binnen de WHO classificatie aan kan worden gehangen, zou 'niet elders te classificeren' (NEC) moeten worden toegevoegd aan de diagnose, bijvoorbeeld histologisch een oligodendrogloom, maar zonder IDH-mutatie: oligodendrogloom, WHO graad 2 (of 3), NEC (Louis, 2018)

Diagnostische groepen

In onderstaande figuur worden de verschillende groepen diffuse gliomen weergegeven (Figuur 1). (kopie uit Weller, 2021)

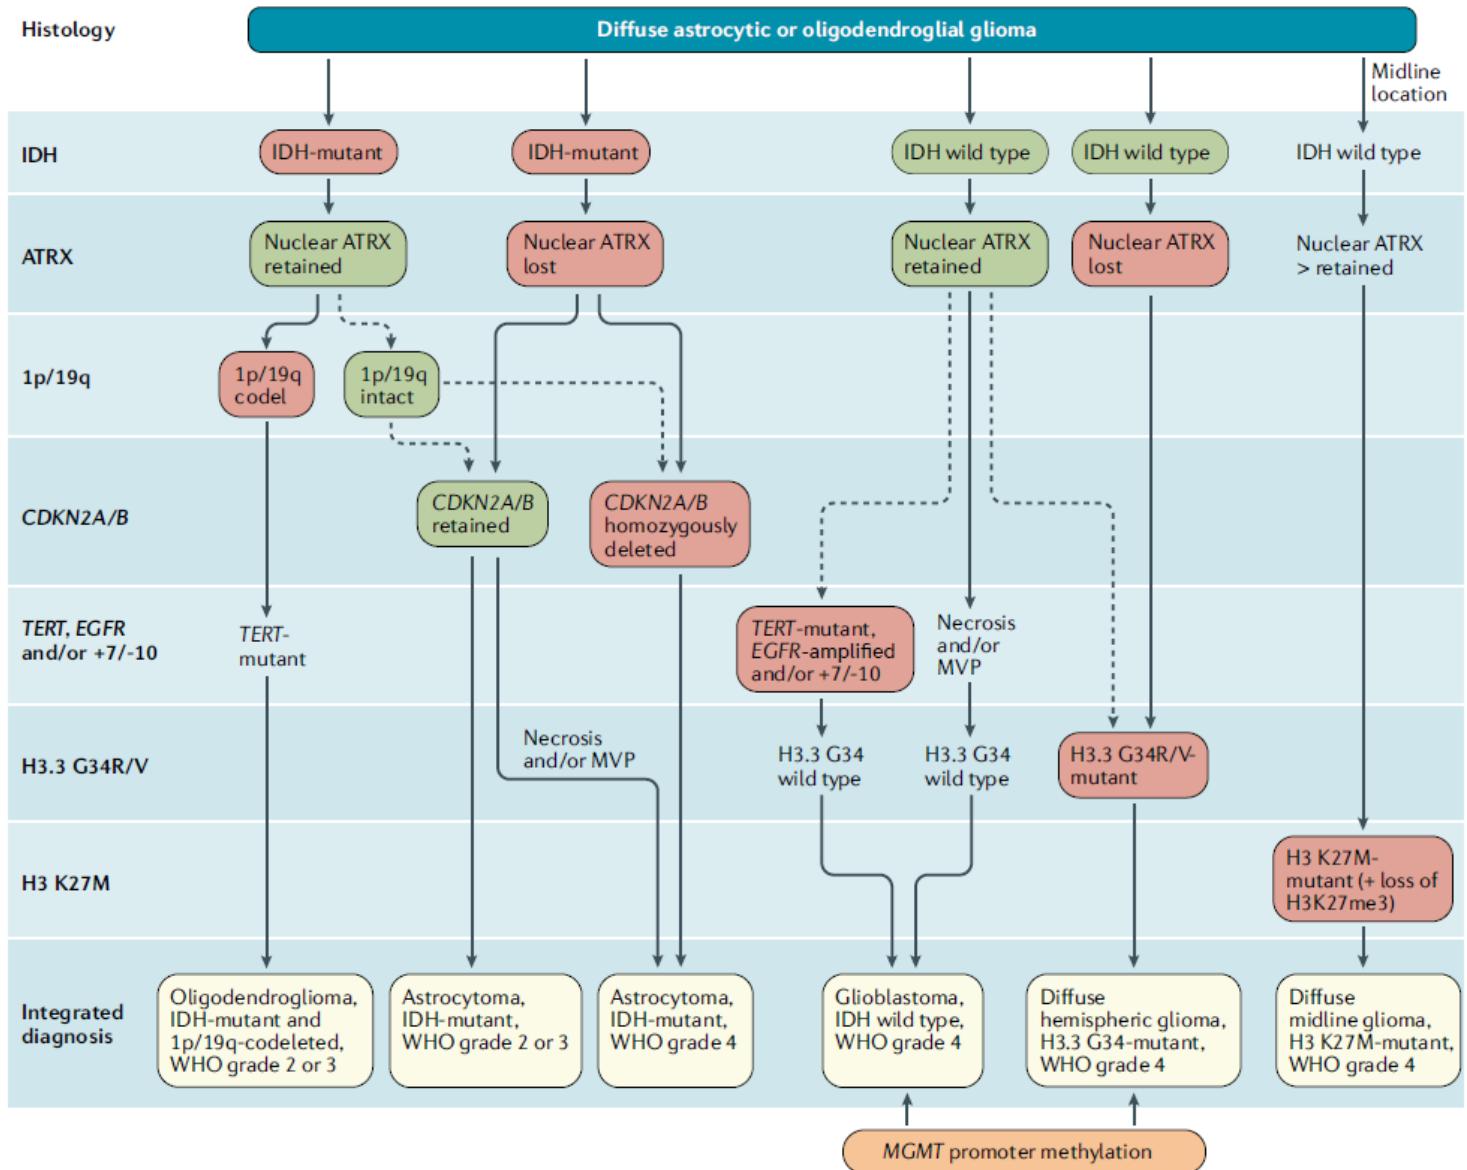

Fig. 1 | Diagnostic algorithm for the integrated classification of the major diffuse gliomas in adults. Tissue specimens obtained through biopsy sampling in patients with diffuse gliomas are routinely assessed by immunohistochemistry for the presence of R132H-mutant IDH1 and loss of nuclear ATRX. In patients aged >55 years with a histologically typical glioblastoma, without a pre-existing lower grade glioma, with a non-midline tumour location and with retained nuclear ATRX expression, immunohistochemical negativity for IDH1 R132H suffices for the classification as IDH-wild-type glioblastoma¹. In all other instances of diffuse gliomas, a lack of IDH1 R132H immunopositivity should be followed by IDH1 and IDH2 DNA sequencing to detect or exclude the presence of non-canonical mutations. IDH-wild-type diffuse astrocytic gliomas without microvascular proliferation or necrosis should be tested for EGFR amplification, TERT promoter mutation and a +7/-10 cytogenetic signature as molecular characteristics of IDH-wild-type glioblastomas². In addition, the presence of histone H3.3 G34R/V mutations should be assessed by immunohistochemistry or DNA sequencing to identify H3.3 G34-mutant diffuse hemispheric gliomas, in particular in young patients with IDH-wild-type gliomas (such as those <50 years of age with nuclear ATRX loss in tumour cells). Diffuse gliomas of the thalamus, brainstem or spinal cord should be evaluated for histone H3 K27M mutations and loss of nuclear K27-trimethylated histone H3 (H3K27me3) to identify H3 K27M-mutant diffuse midline gliomas. The presence and absence of the diagnostically most relevant molecular alterations for each tumour type are highlighted with red and green boxes. MVP, microvascular proliferation.

Gradering van gliomen

In de WHO-classificatie wordt bij de gliomen allereerst onderscheid gemaakt tussen diffuse en circumschrepte gliomen. Circumschrepte gliomen betreffen bijvoorbeeld pilocytaire astrocytomen met een essentieel andere genetische opmaak (geen IDH-mutaties, wel vaak andere mutaties zoals BRAF-KIAA), pleomorf xanthoastrocytoma (PXA) en subependymale reuscel astrocytoma (SEGA). Deze richtlijn betreft alleen de diffuse astrocytaire en oligodendrogliale tumoren; de circumschrepte blijven gezien de zeer lage prevalentie buiten beschouwing. De verschillende diagnostische categorieën zijn weergegeven in tabel 1.

De diffuse gliomen worden allereerst onderverdeeld in gliomen met en zonder IDH-mutatie; de IDH-gemuteerde tumoren worden vervolgens onderverdeeld in astrocytomen of oligodendrogliomen op basis van 1p/19q-status. Oligodendrogliale tumoren zijn per definitie IDH-gemuteerd, dit geldt in de nieuwe classificatie ook voor astrocytomen. IDH-mutant astrocytomen worden verder onderverdeeld in verschillende tumorgraderingen op basis van CDKN2A/B status en histologische kenmerken (microvasculaire proliferatie en necrose). IDH-wildtype gliomen worden glioblastoom genoemd. Patiënten met een graad 4, IDH-mutant astrocytoom hebben een significant betere overleving dan patiënten met een IDH-wildtype glioblastoom. (Shirahata 2018).

Tabel 1 Hoofdgroepen gliomen, conform WHO classificatie 2021

Diagnose	Moleculaire karakteristieken
Oligodendrogioom WHO graad 2	IDH mutant, 1p/19q codeletie
Oligodendrogioom WHO graad 3	IDH mutant, 1p/19q codeletie
Astrocytoom, IDHmut, WHO graad 2	IDH mutant, CDKN2A/B wildtype, frequent ATRX en/of TP53 mutatie
Astrocytoom, IDHmut, WHO graad 3	IDH mutant, CDKN2A/B wildtype, frequent ATRX en/of TP53 mutatie
Astrocytoom, IDHmut, WHO graad 4	IDH mutant, CDKN2A/B homozygote deletie, frequent ATRX en/of TP53 mutatie
Glioblastoom, IDHwt	IDH wildtype, vaak TERT mutatie, EGFR amplificatie, +7/-10
Diffuus 'midline' glioom	IDH wildtype, H3K27 mutatie
Diffuus hemisferisch glioom	H3 G34-mutant

Astrocytoom, IDHmut, WHO graad 2, 3 en 4

In de vorige classificatie (2016) werden er twee soorten diffuse astrocytomen gedefinieerd: astrocytomen IDHmut en astrocytomen IDHwt. In de huidige classificatie is er voor gekozen om alle IDH-mutante diffuse astrocytomen onder dezelfde noemer te scharen (astrocytoom, IDH mutant) en binnen deze groep te graderen als WHO graad 2, 3 of 4. De term glioblastoom is daarmee voor IDH-mutant astrocytomen in onbruik geraakt en alleen nog gereserveerd voor IDH wildtype WHO graad 4 astrocytomen.

IDHmut astrocytomen bestaan uit cellen die de voor astrocyten typische cytoplasmatische uitlopers of een meer afgeronde cytoplasmatische contour hebben (gemistocytair fenotype). De celkern is daarbij vaak

vergroot en kan een abnormale vorm hebben. Zodra de polymorfie en pleomorfie van de cellen sterker zijn en de astrocytaire kenmerken van astrocyten minder duidelijk zijn, veelal in combinatie met een hogere celrijkdom en tevens het frequent voorkomen van mitosen, is de diagnose astrocytoom graad 3 morfologisch van toepassing. Met name de morfologische afgrenzing tussen astrocytoom WHO-graad 2 en astrocytoom WHO-graad 3 is subjectief.

Moleculaire veranderingen

De meeste diffuse astrocytomen hebben naast de kenmerkende IDH-mutaties ook mutaties in TP53 en ATRX. In de context van een astrocytaire tumor met zowel IDH-mutatie als verlies van ATRX-expressie en/of sterke p53-positiviteit kan de diagnose diffuus astrocytoom, IDH-mutant ook gesteld worden zonder testen van 1p/19q (Louis, 2018). Een homozygote deletie van CDKN2A/B is een belangrijke diagnostische en prognostische marker in IDH-mutant astrocytomen. Omdat gebleken is dat een homozygote CDKN2A/B deletie een zeer slechte prognose met zich meebrengt, rechtvaardigt de aanwezigheid van deze mutatie een WHO graad 4 toekenning (astrocytoom, IDH-mutant, WHO graad 4), onafhankelijk van de histologische gradering. (Brat, 2020) Indien dit type tumor geen mutatie in CDKN2A/B heeft, maar histologisch wel microvasculaire proliferaties en/of necrose laat zien, is het nog steeds een graad 4 tumor, maar is de prognose beter dan wanneer er wel een homozygote CDKN2A/B deletie aanwezig is. (Shirahata, 2018)

Oligodendroglioom

Het oligodendroglioom wordt gedefinieerd als een glioom met zowel een IDH-mutatie als het verlies van zowel de hele korte arm van chromosoom 1 en de gehele lange arm van chromosoom 19 (gecombineerd 1p/19q-verlies). De klassieke morfologie bestaat uit cellen met ronde kernen waar omheen cytoplasma, waarin geen intermediaire filamenten voorkomen, en dat door fixatie meestal verdwenen is. Hierdoor ontstaat een honingraatstructuur van het tumorweefsel.

Oligodendroglomen worden onderverdeeld in WHO-graad 2 en WHO-graad 3. Voor de morfologische diagnose oligodendroglioom graad 3 is het voorkomen van microvasculaire proliferatie nodig, al of niet vergezeld door gebieden met necrose. Morfologisch kunnen oligodendroglomen graad 3 overlappen met glioblastomen, die per definitie tot de astrocytaire tumoren behoren, echter de moleculaire eigenschappen zijn leidend voor de diagnose.

Moleculaire veranderingen

Naast de diagnostische combinatie van IDH-mutatie en 1p/19q-codeletie zijn mutaties in de TERT-promotor doorgaans aanwezig. De oligodendrogliale morfologie kan gezien worden bij andere tumoren zoals clearcell ependymomen, neurocytomen, dysembryoplastische neuro-epitheliale tumoren, sommige metastasen, maar deze tumoren missen de 1p/19q-codeletie. Anderzijds kan de oligodendrogliale genetische signatuur ook gevonden worden in tumoren met overwegend astrocytaire morfologie, bijvoorbeeld tumoren met veel gemistocytaire cellen, of in de randen van oligodendroglomen, waar de morfologie van fibrillaire astrocyten kan overheersen. De moleculaire signatuur is echter leidend voor de diagnose en prognose.

Glioblastomen, IDHwt, WHO graad 4

Glioblastomen zijn diffuus infiltrerende astrocytomen van de hoogste maligniteitsgraad (WHO-graad 4), gekenmerkt door kernatypie, mitosen, microvasculaire proliferatie en necrose waarin in wisselende mate nog astrocytaire differentiatie wordt gezien.

Moleculaire veranderingen

Voor IDH-wildtype diffuse astrocytomen geldt dat de aanwezigheid van een *TERT* promotor (*TERTp*) mutatie, en/of een *EGFR* gen amplificatie, en/of +7/-10 een graad 4 toekenning rechtvaardigt. De diagnose *glioblastoom, IDH-wildtype, WHO graad 4* kan worden gesteld in IDH-wildtype gliomen met aanwezigheid van necrose en/of microvasculaire proliferaties, en/of met aanwezigheid van één of meer van genoemde moleculaire afwijkingen (Brat, 2018). Hoewel enige voorzichtigheid betracht dient te worden bij histologisch graad 2 tumoren met enkel een *TERTp* mutatie (Berzero, 2021).

MGMT-promotormethylering

Patiënten met een WHO graad 4 glioom (IDHwt glioblastoom) met een gemethyleerde MGMT-promotor hebben na behandeling met temozolamide mediaan een langere overleving dan patiënten zonder deze methylering (Hegi, 2005; Wick, 2012). Echter ook bij patiënten zonder (aangetoonde) methylering van de MGMT-promotor wordt de mediane overlevingsduur verlengd door behandeling met temozolamide, zij het veel minder uitgesproken (Perry, 2017). Derhalve heeft de methyleringsstatus van MGMT zowel een prognostische als predictieve waarde.

Diagnostische procedure

Histologische beoordeling (laesional, tumor of geen tumor, primair of metastatisch, diffuus of circumschrift, astro- of oligodifferentiatie, WHO-graad) dient altijd plaats te vinden op zo representatief mogelijk materiaal. Het vaststellen van moleculaire kenmerken kan vervolgens op twee manieren gedaan worden. Middels een next generation sequencing (NGS-)panel gericht op gliomen kunnen vrijwel alle voor gliomen relevante moleculaire veranderingen worden opgespoord¹. In geval van een histologisch niet diagnostisch biopt kan moleculaire analyse soms toch een glioom op het spoor komen (Synhaeve, 2018). Een alternatieve en minder kostbare manier om moleculaire veranderingen vast te stellen, is middels immuunhistochemie van gemuteerde of overmatig tot expressie komende eiwitten. Mutatie van IDH1, EGFRvIII, TP53 en H3K27A leidt tot expressie van een gemuteerd eiwit dat middels immuunhistochemie kan worden aangetoond. Ook ATRX-mutatie kan immuunhistochemisch worden aangetoond door verlies van ATRX-expressie en sluit een oligodendroglioom uit (Cancer Genome Atlas research Network, 2015).

¹ MGMT promotormethyleringsstatus wordt meestal in een aparte test bepaald.

De immunohistochemische test voor de expressie van het MGMT-eiwit correleert niet goed met gevoeligheid voor alkylerende chemotherapie (Quillien, 2012).

Conclusie

De uiteindelijke diagnose is een geïntegreerde diagnose op basis van de morfologische en moleculaire kenmerken. De gelaagde diagnose bestaat uit de histologische diagnose (tumorcategorie en WHO-graad), gevolgd door (alle) resultaten uit het moleculair onderzoek.

Onderbouwing

Achtergrond

In de richtlijn gliomen voor 2015 werd de diagnostiek van gliomen nog uitsluitend bepaald door microscopie, eventueel met immunohistochemie. In 2018 werd de richtlijn gereviseerd aan de hand van de criteria zoals neergelegd door de WHO in de gereviseerde vierde editie die in 2016 verscheen (Louis, 2016). In de laatste jaren is de moleculaire karakterisering verder toegenomen en verbeterd. In 2021 is er een nieuwe, vijfde, WHO-classificatie van centraal zenuwstelsel tumoren verschenen. Deze nieuwe classificatie is meegenomen in de herziening van de richtlijn in 2022/2023.

Zoeken en selecteren

Om de uitgangsvraag te kunnen beantwoorden is geen systematische literatuuranalyse verricht maar is de WHO-classificatie (Louis, 2016) gebruikt. Naast deze editie verschenen publicaties van auteurs van de WHO-editie onder de titel cIMPACT-NOW (Consortium to Inform Molecular and Practical Approaches to CNS Tumor Taxonomy – Not Official WHO) waarin additionele, bijgewerkte aanbevelingen worden gedaan. Ook deze publicaties zijn meegenomen in deze modules. In '22/'23 is de module aangepast op basis van de vijfde WHO-classificatie (2021).

Behandeling Laaggradig glioom

Deze module is onderverdeeld in de volgende submodules en sub-submodules:

- Klinisch prognostische factoren laaggradig glioom
- Neurochirurgie
 - Resectie versus watchful waiting
 - Minimale mate van resectie bij laaggradig glioom
- Radio-/Chemo-/systeemtherapie
 - Behandelingen bij laaggradig glioom
 - Recidief laaggradig glioom

Klinisch prognostische factoren laaggradig glioom

Uitgangsvraag

Wat zijn de klinisch prognostische factoren bij het laaggradig glioom?

Aanbeveling

De werkgroep is van mening dat onderstaande factoren nuttig zijn voor een onderbouwde inschatting van de levensverwachting voor patiëntenvoorlichting en/of voor het identificeren van patiënten met een ongunstige levensverwachting voor vroege behandeling bij het laaggradig glioom. Deze prognostische factoren zijn niet gevalideerd voor toepassing als indicatiecriteria voor behandeling:

- hogere leeftijd (afkapwaarde 40 jaar)
- astrocytair subtype
- grotere tumor (afkapwaarde 4 of 5 cm)
- een tumor over de middenlijn
- een slechtere conditie (KPS ≤ 80)
- eloquente lokalisatie van de tumor
- grotere diameter expansie

De werkgroep is van mening dat het bfhouden van een volume diametercurve prognostische informatie kan geven over progressievrije overleving en levensverwachting en van pas kan komen bij timing van behandeling.

Overwegingen

De prognostische factoren kunnen van pas komen om een onderbouwde inschatting van progressievrije overleving en levensverwachting te kunnen geven in het kader van voorlichting. Belangrijk is hierbij te realiseren dat de betrouwbaarheidsintervallen van deze schattingen groot zijn en dus de precisie van deze schattingen van beperkte waarde.

Over het algemeen geldt dat bij aanwezigheid van een of meer ongunstige prognostische factoren vroege behandeling en eventueel combinaties van behandelingen geadviseerd wordt. Daarbij is het belangrijk te realiseren dat onbekend is of de effectiviteit van deze behandelingen verschilt tussen patiënten met een hoger of lager risicoprofiel voor de levensverwachting. Deze prognostische factoren zijn daarom niet gevalideerd voor toepassing als indicatiecriteria voor behandeling.

Het bfhouden van een volume diametercurve in de tijd gedurende de behandeling en follow-up geeft additionele prognostische informatie over progressie en levensverwachting. Dit zou van meerwaarde kunnen zijn voor de timing van vervolgbehandeling, maar dit is niet aangetoond.

Onderbouwing

Conclusies

Het is aannemelijk dat hogere leeftijd (afkapwaarde 40 jaar), astrocytair subtype, en grotere tumor

(afkapwaarde 4 of 5 cm) ongunstige prognostische factoren zijn voor totale overleving en progressievrije overleving.

Pignatti 2002²⁶¹, Gorlia 2013¹¹³, Chang 2008⁵¹, Youland 2013⁴⁰⁴

Het is aannemelijk dat tumoruitbreiding over de middenlijn, een slechtere conditie, eloquente lokalisatie en grotere diameterexpansie ongunstige prognostische factoren zijn.

Chang 2008⁵¹, Pallud 2009²⁴⁶

Samenvatting literatuur

Pignatti [2002²⁶¹] beschreef prognostische factoren voor totale overleving op basis van data van 322 patiënt met een laaggradig glioom uit een klinische studie naar radiotherapie (constructieset) en valideerde de prognostische factoren met data van 288 patiënten met een laaggradig glioom uit een andere klinische studie (validatieset). De mediane follow-up was 6,6 jaar. In de multivariate analyse werden de volgende ongunstige prognostische factoren vastgesteld: leeftijd ≥ 40 jaar, astrocytair subtype, grootste diameter ≥ 6 cm, tumor over de middenlijn en aanwezigheid van neurologische functiestoornis. Een nieuwe analyse van dezelfde constructieset werd beschreven door Gorlia [2013¹¹³] waarbij de aanwezigheid van neurologische functiestoornis, een korte ziektegeschiedenis (<30 wk), astrocytair subtype, en tumordiameter >5 cm werden vastgesteld als ongunstige prognostische factoren voor progressievrije overleving en totale overleving. De factoren werden gevalideerd bij 450 patiënten van twee klinische studies. Drie risicogroepen (low, intermediate en high) werden onderscheiden.

Chang beschreef prognostische factoren voor progressievrije overleving en totale overleving op basis van 281 patiënten met een laaggradig glioom uit een cohort van een centrum. De mediane follow-up was 5,8 jaar. In de multivariate analyse werden deze ongunstige prognostische factoren vastgesteld: eloquente lokalisatie, KPS ≤ 80 , leeftijd >50 jaar en tumordiameter >4 cm [Chang 2008⁵¹]. Chang valideerde deze prognostische factoren bij data van 256 patiënten van drie andere ziekenhuizen. De som van deze prognostische factoren met een weging van 1 per factor correspondeert met vier risicogroepen voor progressievrije overleving en totale overleving.

De studie van Pallud beschrijft de volumetrische diameterexpansie (de diameter van het tumorvolume als bolvorm; $[2 \times \text{volume}]^{1/3}$, in de tijd) als prognostische factor voor maligne progressievrije overleving en totale overleving op basis van 407 patiënten met een laaggradig glioom. De mediane follow-up was 7,2 jaar [Pallud 2012²⁴⁸, Pallud 2013²⁴⁵]. Een expansie van ≥ 8 mm per jaar was een ongunstige prognostische factor voor maligne progressievrije overleving (tijd tot maligne transformatie of overlijden) en totale overleving onafhankelijk van leeftijd, tumorvolume, tumor over de middenlijn, contrastaankleuring en mate van resectie.

De studie van Youland beschrijft een groot cohort van 852 patiënten met een laaggradig glioom. De mediane follow-up was 11,4 jaar. De volgende ongunstige prognostische factoren werden bevestigd in multivariate analyse: leeftijd >40 jaar, astrocytaire subtype, tumordiameter ≥ 5 cm [Youland 2013⁴⁰⁴].

Neurochirurgie bij laaggradig glioom

Deze submodule is onderverdeeld in de volgende sub-submodules:

- Resectie versus watchful waiting
- Minimale mate van resectie bij laaggradig glioom

Verantwoording

Laatst beoordeeld : 15-04-2015

Resectie versus watchful waiting bij laaggradig glioom

Uitgangsvraag

Wat is de beste behandelingsstrategie bij een patiënt met een vermoedelijk laaggradig glioom in termen van kwaliteit van leven, symptoom vrije overleving, progressie vrije overleving, morbiditeit, mortaliteit en totale overleving: resectie versus 'watchfulwaiting'?

Aanbeveling

Voor een patiënt met een vermoedelijk laaggradig glioom dienen de risico's en de voordelen van de verschillende behandelstrategieën, waaronder vroege resectie, biopt of watchful waiting, individueel afgewogen te worden in een multidisciplinaire hersentumorwerkgroep.

De beslissing over de eerste behandelstappen bij een patiënt met een vermoedelijk laaggradig glioom dient in multidisciplinair overleg genomen te worden waarbij tenminste aanwezig is: een neurochirurg met ervaring met intraoperatieve stimulatiemapping van hersenfuncties, een neuroloog met oncologische expertise, een neuroradioloog, een radiotherapeut, een oncoloog en optioneel een klinisch neuropsycholoog. Idealiter wordt in de werkgroep een eerste behandelkeuze met de alternatieven geformuleerd.

De patiënt met een vermoedelijk laaggradig glioom dient daarna zo goed mogelijk geïnformeerd te worden over het natuurlijk beloop en de verschillende behandelmogelijkheden op basis van de recente literatuur. De onzekerheden van het effect van de behandelingen op overleving, kwaliteit van leven, progressievrije overleving, morbiditeit en mortaliteit zijn onderdeel van de voorlichting.

Mogelijke argumenten voor een watchful waiting beleid kunnen bestaan uit:

- twijfel aan de radiologische diagnose diffuus laaggradig glioom (ten opzichte van een benigne aandoening)
- het ontbreken van gerandomiseerd onderzoek naar het verschil in uitkomst tussen watchful waiting en een resectie;
- onzekerheid over het effect van een resectie op cognitie of kwaliteit van leven
- het uitstellen van risico's op morbiditeit en mortaliteit van een vroege resectie
- comorbiditeit die gepaard gaat met hogere morbiditeit en mortaliteit van een resectie.

Mogelijke argumenten voor een biopt kunnen bestaan uit:

- twijfel aan de radiologische diagnose diffuus laaggradig glioom
- het bepalen van moleculaire markers
- de verwachting van een beperkte mate van resectie
- uitgebreide infiltratie die past bij gliomatosis (zie module behandeling Gliomatosis cerebri)
- het vermijden van risico's op morbiditeit en mortaliteit (bijvoorbeeld door comorbiditeit) van een resectie.

Mogelijke argumenten voor een vroege resectie kunnen bestaan uit:

- het verkrijgen van een representatieve histopathologische diagnose
- het bepalen van moleculaire markers
- het verminderen van neurologische en cognitieve symptomen
- het verminderen van epileptische verschijnselen of nastreven van aanvalsvrijheid
- het verlengen van tijd tot progressie
- het verlengen van tijd tot hooggradige dedifferentiatie
- het verlengen van levensverwachting
- het verbeteren van respons op radiotherapie of chemotherapie
- het voorkómen van een resectie van een grotere tumor op hogere leeftijd.

Over het algemeen zal bij een patiënt met één of meer risicofactoren (zie module Klinisch prognostische factoren laaggradig glioom) eerder een vroege resectie overwogen worden.

Onderbouwing

Conclusies

Voor de zoekvraag werd 'watchful waiting' aanvankelijk gedefinieerd als een beleid zonder vroege tumorbehandeling (operatie, bestraling of chemotherapie), zonder een weefseldiagnose bij een vermoedelijk laaggradig glioom op basis van een MRI. Omdat voor deze vraag geen vergelijkende studies werden gevonden, werd de zoekvraag uitgebreid en 'watchful waiting' gedefinieerd als een beleid zonder vroege tumorbehandeling met een weefseldiagnose door een hersenbiopt.

Kritische uitkomstmaten

Voor de overleving van patiënten met een diffuus laaggradig glioom is op basis van het beschikbare bewijs geen directe vergelijking mogelijk tussen vroege resectie en watchful waiting **zonder** biopt, omdat geen vergelijkende studies zijn gevonden.

Er is wetenschappelijk bewijs van lage kwaliteit dat de totale overleving van patiënten met een diffuus laaggradig glioom na vroege resectie langer is dan na watchful waiting **met** een biopt. De invloed van patiëntenselectie hierop is niet vastgesteld.

Pallud 2013²⁴⁷, Jakola 2012¹⁴⁹, Jakola 2013¹⁵⁰, De Mecado Bianco 2012, Sahgal 2013²⁸⁸, Schomas 2009³⁰²

Enkel voor de subgroep van patiënten met een laaggradig astrocytoom in niet-eloquente gebieden is er bewijs van lage kwaliteit dat de totale overleving significant beter is na resectie dan na biopsie, maar bij gebrek aan risicotransfer is deze resultaten onbetrouwbaar.

Bianco 2013¹⁷

Er is geen wetenschappelijk bewijs beschikbaar over het effect van resectie versus biopsie / watchful waiting van een laaggradig glioom op de kwaliteit van leven.

Belangrijke uitkomstmaten

Voor patiënten met een diffuus laaggradig glioom is er bewijs van lage kwaliteit dat de progressievrije overleving na resectie significant beter is dan na biopsie / watchful waiting.

Jakola 2012¹⁴⁹, Jakola 2013¹⁵⁰, Pallud 2013²⁴⁵

Er is geen wetenschappelijk bewijs beschikbaar over het effect van resectie versus biopsie / watchful waiting van een diffuus laaggradig glioom op de symptoomvrije overleving.

Voor patiënten met een diffuus laaggradig glioom is er bewijs van lage kwaliteit dat het aantal neurologische en chirurgische complicaties en de operatieve mortaliteit na resectie niet significant hoger is dan na biopsie / watchful waiting.

Jakola 2013¹⁵⁰, Jakalo 2012¹⁴⁹, Bianco 2013¹⁷

Voor patiënten met een laaggradig glioom is er bewijs van lage kwaliteit dat het aantal maligne transformaties na biopsie / watchful waiting significant hoger is dan na resectie. Bij gebrek aan risicocorrectie zijn deze resultaten echter onbetrouwbaar.

Jakola 2012¹⁴⁹

Samenvatting literatuur

Voor de zoekvraag werd 'watchful waiting' aanvankelijk gedefinieerd als een beleid zonder vroege tumorbehandeling (operatie, bestraling of chemotherapie), zonder een weefseldiagnose bij een vermoedelijk laaggradig glioom op basis van een MRI. Omdat voor deze vraag geen vergelijkende studies werden gevonden, werd de zoekvraag uitgebreid en 'watchful waiting' gedefinieerd als een beleid zonder vroege tumorbehandeling met een weefseldiagnose door een hersenbiops. Diffuus laaggradig glioom werd gedefinieerd als WHO graad II glioom, zoals astrocytoom, oligodendroglioom of oligoastrocytoom (te onderscheiden van WHO graad I gliomen, zoals pilocytair astrocytoom, ganglioglioom of dysembryoplastic neuro-epitheliale tumor). Publicaties werden geïncludeerd indien gepubliceerd na 2003 en met tenminste 30 patiënten.

Met deze zoekvraag werden een Cochrane review [Veeravagu 2013³⁶⁴] en vier vergelijkende observationele studies, beschreven in vijf publicaties [Jakola 2012¹⁴⁹, Jakola 2013¹⁵⁰, De MecadoBianco 2012, Sahgal 2013²⁸⁸, Schomas 2009³⁰¹] geïdentificeerd. Na het uitwerken van de zoekvraag (23 oktober 2013) werd nog een vijfde studie gepubliceerd die aan de criteria voldeed [Pallud 2013²⁴⁵].

Kwaliteit van het bewijs

De Cochrane review is van goede kwaliteit. Het risico op bias in de vijf vergelijkende observationele studies is hoog. De vijf studies zijn retrospectief uitgevoerd. De vijf studies rapporteerden allen risicofactoren. Twee studies corrigeerden voor risicofactoren in de analyse voor totale overleving [Jakola 2012¹⁴⁹, Pallud 2013²⁴⁵]. In geen enkele observationele studie werden de uitkomsten blind beoordeeld. In alle studies was selectiebias aanwezig (selection on indication). Hierdoor zijn de gerapporteerde verschillen weinig betrouwbaar.

Gewenste effecten

Effect op totale overleving (cruciale uitkomst)

In zes publicaties van vijf studies werd het effect op de totale overleving vergeleken tussen resectie en

watchful waiting.

Een Cochrane review beoordeelde studies naar de klinische effectiviteit van een hersenbiopt vergeleken met resectie bij nieuwe patiënten met een vermoedelijk laaggradig glioom [Veeravagu 2013³⁶⁴]. Veeravagu vond geen gerandomiseerde gecontroleerde studies over deze vraag en beschrijft twintig studies die niet aan de criteria voldeden in meer detail. De Cochrane review concludeert dat behandelaars vanwege het ontbreken van gerandomiseerde studies voor elke patiënt de risico's en de voordelen van elke interventie individueel moeten wegen totdat meer bewijs beschikbaar is.

Jakola [2013¹⁵⁰] beschrijft een populatiestudie met parallelle consecutieve cohorts bestaande uit 153 patiënten met een supratentorieel diffuus laaggradig glioom (WHO graad II) tussen 1998 en 2009 en een mediane follow-up van 7 jaar: 66 patiënten uit een kliniek met een behandelvoorkleur voor watchful waiting met biopt (47 ondergingen een biopt, 19 een vroege resectie) en 87 patiënten uit een kliniek met een behandelvoorkleur voor vroege resectie (12 ondergingen een biopt, 75 een vroege resectie). De mediane overleving in de kliniek met watchful waiting voorkeur was 5,9 jaar (95%CI 4,9 -7,3). De mediane overleving in de kliniek met vroege resectie voorkeur werd in 10 jaar follow-up niet bereikt. De totale overleving was significant verschillend in het voordeel van de kliniek met vroege resectie voorkeur (log-rank p=0,01). De 5-jaarsoverleving bedroeg 60% in de kliniek met watchful waiting voorkeur versus 74% in de kliniek met vroege resectie voorkeur; de 7-jaarsoverleving bedroeg respectievelijk 44% en 68%. In de multivariate analyse met correctie voor risicofactoren (leeftijd, preoperatieve tumor diameter, midlijn betrokkenheid, histologische typering en neurologische symptomatologie) was de overleving ook significant verschillend in het voordeel van de kliniek met vroege resectie voorkeur (HR 1,8; 95%CI 1,1-2,9; p=0,03).

Jakola beschrijft een subgroepanalyse gebaseerd op dezelfde studie [Jakola 2013¹⁵⁰] van de 117 patiënten met een laaggradig astrocytoom: 55 uit de kliniek met een behandelvoorkleur voor watchful waiting (43 ondergingen een biopt, 12 een vroege resectie), 62 uit de kliniek met een behandelvoorkleur voor vroege resectie (11 ondergingen een biopt 51 een vroege resectie). De mediane overleving in de kliniek met watchful waiting voorkeur was 5,6 jaar (95%CI 3,5-7,6). De mediane overleving in de kliniek met vroege resectie voorkeur was 9,7 jaar (95%CI 7,5-11,9). De totale overleving was significant verschillend in het voordeel van de vroege resectie kliniek (log-rank p=0,047). De 5-jaarsoverleving bedroeg 56% in de kliniek met watchful waiting voorkeur versus 66% in de kliniek met vroege resectie voorkeur; de 7-jaarsoverleving bedroeg 39% en 64%, respectievelijk. In multivariate analyse met correctie voor risicofactoren (leeftijd, Karnofsky, preoperatieve tumor diameter, vroege radiotherapie) was de overleving ook significant verschillend in het voordeel van vroege resectie voorkeur (HR 1,77; 95%CI 1,02-3,05; p=0,041).

De MacedoBianco beschrijft een cohort bestaande uit 82 patiënten met een hemisferisch laaggradig astrocytoom tussen 1999 en 2008 met een mediane follow-up van 5 jaar [De MacedoBianco 2013]. Voor tumoren in niet-eloquente gebieden werd een langere overleving gevonden bij 33 patiënten na vroege resectie vergeleken met 9 patiënten na biopsie (4,7 versus 1,9 jaar, p=0,013). Voor tumoren in eloquente gebieden werd geen verschil in overleving gevonden tussen 23 patiënten na vroege resectie en 17 patiënten biopsie (4,5 versus 2,1 jaar; p=0,33).

Sahgal beschrijft een cohort van verschillende universiteitsziekenhuizen, bestaande uit 182 patiënten met een laaggradig astrocytoom tussen 1992 en 1996 en met een niet- beschreven follow-up duur [Sahgal 2013²⁸⁸]. De gemiddelde overleving was 5,5 jaar voor 84 patiënten na vroege resectie en 3,4 jaar voor 98 patiënten na biopsie; statistische analyse werd niet gerapporteerd.

Schomas beschrijft een subgroepanalyse van een cohort van de Mayo Clinic, Rochester, VS, bestaande uit 32 patiënten ouder dan 55 jaar met een niet-pilocytair laaggradig glioom tussen 1960 en 1992 en een mediane

follow-up van 17 jaar [Schomas 2009b³⁰²]. De mediane overleving van 16 patiënten na een vroege resectie was 3,0 jaar en van 16 patiënten na een biopt was 2,2 jaar ($p=0,57$).

Pallud beschrijft een cohort van verschillende universiteitsziekenhuizen bestaande uit 1509 patiënten met een diffuus laaggradig glioom tussen 1992 en 2011 en een mediane follow-up van 7 jaar. Ten opzichte van 619 patiënten na biopt bestond geen verschil in overleving van 427 patiënten na partiële resectie (HR 0,95; 95%CI 0,76-1,19, $p=0,663$), een langere overleving van 313 patiënten na subtotalresectie (HR 0,62; 95%CI 0,47-0,82, $p=0,001$, en een langere overleving van 150 patiënten na totale resectie (HR 0,32; 95%CI 0,20-0,53, $p<0,001$). In de multivariate analyse met correctie voor risicofactoren (geslacht, leeftijd, epilepsie, preoperatieve tumor diameter, midlijn betrokkenheid, tumor lokalisatie, pathologische typering, radiotherapie en chemotherapie) bestond ten opzichte van de patiënten na biopt geen verschil in overleving na partiële resectie (HR 1,10; 95%CI 0,87-1,40; $p=0,409$) of na subtotalresectie (HR 0,81; 95%CI 0,59-1,10; $p=0,169$), wel na totale resectie (HR 0,51; 95%CI 0,30-0,88; $p=0,016$).

Kwaliteit van leven (cruciale uitkomst)

In geen van de gevonden studies werd het effect op kwaliteit van leven vergeleken tussen resectie en watchful waiting.

Effect op progressievrije overleving (belangrijke uitkomst)

In drie publicaties van twee studies werd het effect op progressievrije overleving vergeleken tussen resectie en watchful waiting [Jakola 2012¹⁴⁹, Jakola 2013¹⁵⁰, Pallud 2013²⁴⁵].

Jakola [Jakola 2012¹⁴⁹] beschrijft voor patiënten met een diffuus laaggradig glioom een significant verschil in progressie (nieuwe contrastaankleuring op MRI of WHO graad III/IV in nieuwe histopathologie) tussen biopt en vroege resectie. Progressie werd geobserveerd in 56% van de 66 patiënten uit een kliniek met watchful waiting voorkeur vergeleken met 37% van de 87 patiënten uit een kliniek met vroege resectie voorkeur gedurende de follow-up ($p=0,02$). In de subgroep van patiënten met een laaggradig astrocytoom beschrijft Jakola [Jakola 2013¹⁵⁰] geen verschil in progressie tussen 56% van 66 patiënten uit een kliniek met watchful waiting voorkeur vergeleken met 43% van de 62 patiënten uit een kliniek met vroege resectie voorkeur gedurende de follow-up ($p=0,163$).

Pallud [Pallud 2013²⁴⁵] beschrijft voor patiënten met een diffuus laaggradig glioom een significant verschil in progressie (nieuwe contrastaankleuring op MRI of WHO graad III/IV in nieuwe histopathologie) tussen biopt en vroege resectie. Ten opzichte van 619 patiënten na biopt bestond een significant verschil in progressie met 427 patiënten na partiële resectie (HR 0,83; 95%CI 0,71-0,97; $p=0,019$), met 313 patiënten na subtotalresectie (HR 0,51; 95%CI 0,42-0,62; $p<0,001$) en met 150 patiënten na totale resectie (HR 0,29; 95%CI 0,21-0,41; $p<0,001$). In de multivariate analyse met correctie voor risicofactoren bestond ten opzichte van de patiënten na biopt ook een significant verschil in progressie na partiële resectie (HR 0,68; 95%CI 0,58-0,81; $p<0,001$), na subtotalresectie (HR 0,43; 95%CI 0,35-0,53; $P<0,001$) en na totale resectie (HR 0,22; 95%CI 0,16-0,32; $p<0,001$).

Ongewenste effecten

Twee studies rapporteerden over neurologische complicaties na de ingreep [Jakola 2012¹⁴⁹, Jakola 2013¹⁵⁰, Bianco 2013¹⁷]. Jakola vond geen significant verschil in nieuwe of toegenomen neurologische afwijkingen binnen de 30 dagen na de ingreep (biopsie / watchful waiting 18% versus resectie 21%; $p=0,70$) [Jakola 2012a¹⁴⁹]. Ook in de subgroep van 117 patiënten met een laaggradig astrocytoom vonden ze geen significant

verschil (13% versus 21%; $p=0.27$) [Jakola 2013¹⁵⁰]. Bianco rapporteerde een nieuwe blijvende neurologische afwijking ten gevolge van de chirurgische ingreep bij 5% van de patiënten, maar zonder een vergelijking tussen de twee behandelgroepen te rapporteren [Bianco 2013¹⁷].

Dezelfde twee studies rapporteerden ook over de perioperatieve mortaliteit. Jakola rapporteerde geen significant verschil in 30-dagen mortaliteit tussen beide behandelgroepen (biopsie / watchful waiting 1% versus resectie 0%; $p=0.25$) [Jakola 2012¹⁴⁹]. Bianco vond geen operatieve mortaliteit voor de totale populatie [Bianco 2013¹⁷].

Jakola vond geen significant verschil in chirurgische complicaties (biopsie / watchful waiting 9% versus resectie 8%; $p=0.82$), zonder een goede definitie van deze complicaties te geven [Jakola 2012a¹⁴⁹]. Bianco rapporteerde een chirurgische infectie bij 2% van de patiënten, maar zonder een vergelijking tussen de twee behandelgroepen te rapporteren [Bianco 2013¹⁷].

Tenslotte, Jakola rapporteerde significant meer maligne transformaties in de biopsiegroep (56% versus 37%, $p=0.02$), maar zonder de cijfers te corrigeren voor risicofactoren [Jakola 2012a¹⁴⁹].

Aanvullende consensus based samenvatting van de literatuur

Achtereenvolgens worden beschreven: andere (internationale) richtlijnen met aanbevelingen voor het beleid bij diffuus laaggradig glioom, de literatuur van vóór 2004, observationele cohort studies van resectie of watchful waiting, reviews over morbiditeit of mortaliteit van resectie of biopt en literatuur over een aantal behandeldilemma's.

Twee recente richtlijnen zijn gepubliceerd over het beleid bij diffuus laaggradig glioom en doen aanbevelingen voor de behandeling van het vermoedelijk laaggradig glioom op basis van een systematische literatuursearch.

De richtlijn van de European Association for Neuro-Oncology doet aanbevelingen op basis van level B bewijs [Soffietti 2010³²⁰]. In deze richtlijn wordt resectie als eerste behandeloptie geadviseerd, met als doel aan de ene kant maximaliseren van tumorverwijdering, en aan de andere kant minimaliseren van postoperatieve morbiditeit. Een biopt (stereotactisch of open) zou kunnen plaatsvinden met als doel een histologische diagnose, als een operatie niet haalbaar is (door de lokalisatie, uitgebreidheid of comorbiditeit).

De National Comprehensive Cancer Network beveelt, indien mogelijk, een maximale resectie aan met vaststellen van de mate van resectie door een MRI binnen 72 uur na operatie [NCCN 2013²²⁵].

In de literatuur vóór 2004 werd een resectie vergeleken met watchful waiting met een biopt in zes niet-gerandomiseerde vergelijkende observationele studies [Shaw 2002³⁰⁸, Jeremic 1998¹⁵⁹, Van Veelen 1998³⁶², Rajan 1994²⁷⁰, Philippon 1993²⁵⁹, North 1990²³²]. In vijf van de zes studies werd een verschil beschreven in totale overleving ten gunste van resectie, vergeleken met een biopt; in twee van de studies werd gecorrigeerd voor risicofactoren. In één studie werd een verschil in progressievrije overleving vastgesteld ten gunste van een uitgebreidere resectie.

Shaw includeerde 211 patiënten tussen 1986 en 1994 met een laaggradig glioom in een gerandomiseerde studie naar lage en hoge dosis radiotherapie [Shaw 2002³⁰⁸]. Na vijf jaar was 71% van 103 patiënten na biopsie in leven, vergeleken met 56% van 71 patiënten na een subtotaal resectie en met 88% van 29 patiënten na een totale resectie ($p=0,0151$) na een mediane follow-up van 6,4 jaar. Tussen een totale resectie en biopt (HR 0,38; $p=0,07$) en tussen subtotaal resectie en biopt (HR 1,03; $p=0,89$) werd geen significant verschil in overleving gevonden in multivariate analyse met correctie voor risicofactoren (leeftijd,

preoperatieve tumor diameter, midlijn betrokkenheid, pathologische typering, radiotherapie en instituut). Jeremic includeerde 37 patiënten tussen 1988 en 1993 met een supratentorieel laaggradig glioom [Jeremic 1998¹⁵⁹]. Na vijf jaar was 58% van 19 patiënten na biopsie in leven, vergeleken met 94% van 14 patiënten na een resectie ($p=0,009$) met een mediane follow-up van 6,2 jaar.

Van Veelen includeerde 90 patiënten tussen 1975 en 1989 met een supratentorieel laaggradig glioom [Van Veelen 1998³⁶²]. Na vijf jaar was 33% van 18 patiënten na biopsie in leven, vergeleken met 18% van 59 patiënten na een resectie <75% en met 62% van 13 patiënten na een resectie >75% ($P<0,001$). Na 5 jaar was 28% na biopsie progressievrij, vergeleken met 10% na een resectie <75% en 46% na een resectie >75% ($p<0,001$).

Rajan includeerde 82 patiënten met een laaggradig glioom [Rajan 1994²⁷⁰]. De overleving na vijf jaar was 90% bij 11 patiënten na een totale resectie, 52% bij 30 patiënten na subtotale resectie, 50% na partiële resectie en 42% na een biopsie ($p<0,05$) met een mediane follow-up van 4,2 jaar.

Philippon includeerde 174 patiënten tussen 1978 en 1987 met een supratentorieel laaggradig astrocytoom. Na vijf jaar was 45% van 33 patiënten na een biopsie in leven, 50% van 69 patiënten na een subtotale resectie en 80% van 16 patiënten na totale resectie ($p=0,00022$). De operatieve behandeling was een significante prognostische factor voor overleving ($p<0,01$) in multivariate analyse met correctie voor de risicofactoren (leeftijd, lokalisatie, lateralisatie, contrast aankleuring, cyste, histologie en radiotherapie).

North includeerde 77 patiënten tussen 1975 en 1984 met een supratentorieel laaggradig glioom [North 1990²³²]. Na vijf jaar was 43% van 26 patiënten na biopsie in leven, vergeleken met 64% van 43 patiënten na een subtotale resectie en met 85% van 8 patiënten na een totale resectie ($p=0,002$) met een mediane follow-up van 5,8 jaar.

In de literatuur werden niet-vergelijkende observationele studies beschreven waarin de patiënten die een biopsie ondergingen werden ingedeeld bij patiënten met een beperkte resectie, of waarin de mate van resectie als continue variabele werd geanalyseerd, of waarin patiënten na meer of minder uitgebreide resectie werden beschreven [Capelle 2013⁴³, Youland 2013⁴⁰⁴, Jung 2011¹⁶⁰, Ahmadi 2009², Smith 2008³¹⁹, McGirt 2008²¹⁴, Schomas 2009³⁰¹, Claus 2005⁶², Karim 1996¹⁶³, Laws 1984¹⁹⁷]. In negen van de tien niet-vergelijkende observationele studies werd een verschil in totale overleving vastgesteld ten gunste van uitgebreidere resectie, met in zeven studies correctie voor risicofactoren. In vier van de zes niet-vergelijkende observationele studies werd een verschil in progressievrije overleving vastgesteld ten gunste van uitgebreidere resectie, met in vier studies correctie voor risicofactoren.

Capelle includeerde 1097 patiënten tussen 1985 en 2007 met een laaggradig glioom [Capelle 2013⁴³], waarvan 272 patiënten na biopsie, 332 na een resectie met een tumorrest >10 ml, 262 na een resectie met een tumorrest 0-10 ml en 80 na een totale resectie op basis van MRI. De totale overleving is in univariate analyse sterk geassocieerd met het percentage tumorverwijdering ($p<0,0001$) met een mediane follow-up van 7,4 jaar. In de multivariate analyse is overleving eveneens geassocieerd met de mate van tumorverwijdering (RR 0,569; 95%CI 0,382-0,847; $p=0,0199$) met correctie voor risicofactoren (leeftijd, Karnofsky, lokatie, preoperatief tumorvolume, epilepsie).

Youland includeerde 852 patiënten tussen 1960 en 2011 met een laaggradig glioom [Youland 2013⁴⁰⁴], waarvan 321 na biopsie, 211 na totale resectie op basis van MRI, 85 na resectie van 90-99%, en 235 na resectie <90%. Na tien jaar was 60% van 296 patiënten na resectie >90% in leven en 33% van 556 patiënten na resectie <90% ($p<0,0001$) met een mediane follow-up van 11,4 jaar. Na tien jaar was 34% van 296 patiënten na resectie >90% progressievrij en 16% van 556 patiënten na resectie <90% ($p<0,0001$). In de

multivariate analyse is er een verschil in overleving (HR 0,51; 95%CI 0,40-0,65; p<0,0001) en in progressievrije overleving (HR 0,44; 95%CI 0,36-0,54; p<0,0001) ten gunste van een resectie >90% in vergelijking met een resectie <90% met correctie voor risicofactoren (leeftijd, hoofdpijn, epilepsie, taalstoornis, sensomotorische stoornis, histologische subtypering, preoperatieve tumorgrootte, diepe ligging, contrastaankleuring, radiotherapie en chemotherapie).

Jung includeerde 86 patiënten tussen 2000 en 2009 met een laaggradig glioom [Jung 2012], waarvan 40 patiënten na 'totale' resectie, 22 na 'subtotale' resectie en 24 na 'partiële' resectie of biopt. Het type operatie was geassocieerd met overleving (p<0,001) en met progressievrije overleving (p=0,001). De overleving is niet geassocieerd met type operatie met correctie voor risicofactoren (leeftijd, Karnofsky, lokalisatie, histologische subtypering, radiotherapie). In vergelijking met 'partiële' resectie of biopt is de progressievrije overleving gunstiger na 'totale' resectie (HR 0,312; 95%CI 0,101-0,966; p=0,043) met correctie voor risicofactoren (lokalisatie, diffuus groeipatroon, histologische subtypering, radiotherapie).

Ahmadi includeerde 130 patiënten tussen 1985 en 2003 met een laaggradig glioom [Ahmadi 2009²]. De totale overleving bij 91 patiënten na totale resectie was gunstiger dan bij 39 patiënten na partiële resectie of biopt (Logrankp=0,024) met een mediane follow-up van 7,8 jaar. De hazard ratio verschildde ten gunste van totale resectie (HR 4,179; 95%CI 1,527-11,435) na correctie voor de risicofactoren (histologie, lokalisatie en chemotherapie).

Smith includeerde 216 patiënten tussen 1989 en 2005 met een laaggradig glioom, waarbij biopten werden geëxcludeerd [Smith 2008³¹⁹]. Postoperatieve tumorrest (in mL) gemeten op MRI was geassocieerd met overleving (HR 1,010; 95%CI 1,001-1,019, p=0,03) en met progressievrije overleving (HR 1,007; 95%CI 1,001-1,014; p=0,035) in multivariate analyse met correctie voor risicofactoren (leeftijd, Karnofsky, lokalisatie, histologische subtypering) met een mediane follow-up van 4,4 jaar. Het percentage tumorverwijdering was geassocieerd met overleving (HR 0,972; 95%CI 0,960-0,983; p<0,001) in multivariate analyse met correctie voor risicofactoren, en niet met progressievrije overleving (HR 0,992; 95%CI 0,984-1,001; p=0,088).

McGirt includeerde 170 patiënten tussen 1996 en 2007 met een laaggradig glioom [McGirt 2008²¹⁴], waarvan 65 patiënten na totale resectie op basis van MRI, 39 na een bijna totale resectie met <3 mm resttumor en 66 na subtotale resectie met >3 mm resttumor. Na vijf jaar was 95% van 65 patiënten na totale resectie in leven, 80% van 39 na bijna totale resectie en 70% van 66 na subtotale resectie met een mediane follow-up van 4 jaar. Na tien jaar was dit 76%, 57% en 49%, respectievelijk. In vergelijking met patiënten na een subtotale resectie was de overleving na een totale resectie gunstiger (HR 0,36; 95%CI 0,16-0,84, p=0,017) met correctie voor risicofactoren (leeftijd, Karnofsky, histologische subtypering, preoperatieve, tumordiameter), maar niet na een bijna totale resectie. De mediane progressievrije overleving na totale resectie was 7 jaar, na bijna totale resectie 4 jaar en na subtotale resectie 3,5 jaar. In vergelijking met patiënten na een subtotale resectie was de progressievrije overleving na een totale resectie gunstiger (HR 0,56; 95%CI 0,32-0,98, p=0,043) in multivariate analyse met correctie voor risicofactoren (leeftijd, Karnofsky, histologische subtypering, preoperatieve, tumordiameter), maar niet na een bijna totale resectie.

Schomas includeerde 134 patiënten tussen 1960 en 1992 met een laaggradig glioom, waarvan 41 patiënten na 'totale' resectie, 33 na 'radicale subtotale' resectie, 130 na subtotale resectie en 110 na biopsie [Schomas 2009a³⁰¹]. Na tien jaar was 30% van 240 patiënten na 'subtotale' resectie of biopt in leven vergeleken met 57% van 74 patiënten na uitgebreidere resectie (p<0,001) met een mediane follow-up van 13,6 jaar. Een uitgebreidere resectie was geassocieerd met totale overleving (RR 0,63; 95%CI 0,48-0,79; p=0,03) in multivariate analyse met correctie voor risicofactoren (tumorgrootte, histologische subtypering, symptomatologie, radiotherapie). Na tien jaar was 21% van 240 patiënten na 'subtotale' resectie of biopt

progressievrij vergeleken met 47% van 74 patiënten na uitgebreidere resectie ($p<0,001$). Een uitgebreidere resectie was geassocieerd met progressievrije overleving (RR 0,74; 95%CI 0,55-0,96; $p<0,001$) met correctie voor de risicofactor tumorgrootte.

Claus includeerde 156 patiënten tussen 1997 en 2003 met een laaggradig glioom [Claus 2005⁶²]. Geen verschil werd gevonden tussen minder dan totale resectie en totale resectie in totale overleving (HR 4,9; 95%CI 0,61-40) of progressievrije overleving (HR 1,4; 95%CI 0,7-3,1) na correctie voor leeftijd met een mediane follow-up van 3 jaar.

Karim includeerde 379 patiënten in een gerandomiseerde studie naar lage dosis versus hoge dosis radiotherapie [Karim 1996¹⁶³]. De mate van tumorverwijdering (156 patiënten na biopsie of <50% resectie, 103 patiënten na 50-89% resectie en patiënten na resectie >90%) was geassocieerd met overleving ($p<0,01$) en met progressievrije overleving ($p<0,001$), ook in multivariate analyse met correctie voor risicofactoren (leeftijd, conditie, en histologie) ($p<0,05$) met een mediane follow-up van 6,2 jaar.

Laws includeerde 461 patiënten tussen 1915 en 1975 met een supratentoriaal laaggradig glioom. Na 5 jaar was 32% van 356 patiënten na een biopt of 'subtotale' resectie in leven, vergeleken met 44% van 48 patiënten na 'radicale subtotale' resectie en met 61% van 57 patiënten na 'totale' resectie ($p<0,0001$).

In de literatuur werden twee niet-vergelijkende observationele studies beschreven met patiënten die watchful waiting zonder biopt ondergingen [Reijneveld 2001²⁷⁷, Recht 1992²⁷⁴].

Reijneveld includeerde 24 patiënten tussen 1998 en 1999 met een vermoedelijk laaggradig glioom op basis van beeldvorming en matchen deze cases met 24 controle patiënten met een laaggradig glioom na biopt of resectie. Er werd geen verschil gevonden in Barthel Index, Neurologic Functional Status Scale, Karnofsky Performance Scale en Cognitive Functioning Scale. In één van acht domeinen (vitaliteit, $p<0,05$) van de SF-38, in twee van elf domeinen (motor dysfunctie, blaascontrole) van de BCM-20 en in een van vier domeinen (psychomotor functioneren, $p<0,005$) van de Cognitive Performance Status werd een verschil gevonden ten gunste van watchful waiting zonder biopt. Totale overleving of progressie-vrije overleving werd niet geanalyseerd.

Recht includeerde 26 patiënten met een vermoedelijk laaggradig supratentoriaal glioom op basis van CT of MRI die geen vroege behandeling ondergingen en 20 patiënten met een supratentoriaal laaggradig glioom die vroege behandeling ondergingen [Recht 1992²⁷⁴]. Bij 15 van 26 patiënten die aanvankelijk geobserveerd werden, vond na uitstel van 4 tot 123 maanden alsnog een operatie plaats vanwege groei (4), epilepsie (4), symptomatologie (3), en maligne transformatie (3). Bij 9 van 15 uitgestelde operaties werd een hooggradig glioom vastgesteld (5 WHO graad III en 4 WHO graad IV). In 11 van 26 patiënten vond na 15 tot 98 maanden observatie plaats. Er werd geen verschil in overleving gevonden ($p=0,65$) met een mediane follow-up van 3,8 jaar.

Een aantal reviews beschrijft argumenten die betrokken kunnen worden bij een behandeladvies voor patiënten met een laaggradig glioom.

In een systematische review werd het therapeutisch effect van mate van resectie bij glioom beschreven, onder andere voor laaggradig glioom [Sanai 2008²⁹¹]. Sanai identificeerde drie studies met volumetrische data op basis van MRI metingen na operatie voor laaggradig glioom, waarvan drie studies een gunstiger 5-jaarsoverleving beschreven na uitgebreidere resecties.

In een meta-analyse werd de neurologische morbiditeit en mortaliteit van resectie bij glioom beschreven [De Witt Hamer 2012⁷⁶]. Op basis van 90 publicaties met 8091 patiënten werd een permanente nieuwe

neurologische functiestoornis beschreven bij 7,1% (95%CI 5,3-9,0%), een permanent ernstige functiestoornis bij 4,6% (95%CI 3,3-6,1%) en operatieve mortaliteit bij 0,26% (95%CI 0,01-0,50%). Resecties met intraoperatieve stimulatie mapping van hersenfuncties gingen gepaard met minder permanent ernstige neurologische functiestoornissen dan resecties zonder stimulatie mapping (OR 0,39; 95%CI 0,23-0,64). In een review werden de effecten van resectie op de cognitie beschreven en werd geconcludeerd dat dit niet systematisch onderzocht is, maar dat zowel verbetering als achteruitgang werd waargenomen [Klein 2012¹⁷⁷]. Satoer includeerde 45 patiënten met een resectie van een glioom met eloquente lokalisatie, waarvan 27 met een laaggradig glioom [Satoer 2014²⁹⁸]. In vergelijking met gezonde controles onderpresteerden patiënten met een laaggradig glioom voor en na operatie in alle cognitieve domeinen. Drie maanden na operatie trad cognitieve verbetering op voor geheugen (verbalrecall: $t=-1,931$; $p=0,034$) en cognitieve achteruitgang voor taal (category fluency: $t=2,517$; $p=0,030$) ten opzichte van preoperatief. Tussen 3 maanden en 1 jaar na operatie verbeterde de taal (naming: $t=-2,781$; $p=0,026$ en letter fluency: $t=-1,975$; $p=0,047$). Ernstige cognitieve achteruitgang werd niet waargenomen (taal, geheugen, aandacht en executie).

Een review over de morbiditeit en mortaliteit van een biopsie bij glioom werd niet gevonden. In twee publicaties na 2003 met meer dan 100 patiënten werd morbiditeit en mortaliteit van een biopsie beschreven. McGirt beschreef een permanente nieuwe neurologische functiestoornis bij 13 (5%) en postoperatieve mortaliteit bij 3 (1%) van 270 patiënten na een hersenbiopsie [McGirt 2005²¹⁶]. Kongkham beschreef een permanente neurologische functiestoornis bij 9 (1,5%) en postoperatieve mortaliteit bij 8 (1,3%) van 622 patiënten na een hersenbiopsie [Kongkham 2008¹⁸⁰].

De radiologische diagnose 'vermoedelijk laaggradig glioom' op basis van MRI is niet accuraat volgens de literatuur. Scott beschreef bij 21 (36%) van 58 patiënten met vermoedelijk laaggradig glioom op basis van afwezigheid van contrastaankleuring een histologische gradering van WHO graad III [Scott 1992]. Meyer beschreef bij 12 (46%) van 26 patiënten met vermoedelijk laaggradig glioom een histologische gradering van WHO graad III [Meyer 2001²¹⁷]. Pallud beschreef bij 143 (16%) van 927 patiënten met een WHO graad II glioom contrastaankleuring [Pallud 2009²⁴⁶].

De histologische diagnose na een biopsie komt niet overeen met de histologische diagnose na een resectie volgens de literatuur: Jackson beschrijft bij 40 (49%) van 82 patiënten na een biopsie voor een glioom een andere histologische diagnose na resectie binnen 60 dagen na het biopsie [Jackson 2001¹⁴⁷]. Dit had therapeutische consequenties bij 27 (33%) patiënten. Bij 13 (72%) van 18 patiënten met een histologische diagnose WHO graad II na biopsie was sprake van een WHO graad III of IV. Jackson reviewde 6 studies en concludeerden dat de diagnostische precisie van een biopsie 62-95% was in vergelijking met een histologische diagnose op materiaal van een resectie.

Tot slot komt een aantal behandeldilemma's in de praktijk voor, dat gepaard gaat met meer onzekerheid over de behandelstrategie op basis van de literatuur: ten eerste een vermoedelijk laaggradig glioom als toevalsbevinding op beeldvorming, ten tweede een supratotale resectie voor een vermoedelijk laaggradig glioom.

Beeldvorming bijvoorbeeld na een neurotrauma of de controlegroep in radiologisch onderzoek doet een laaggradig glioom als toevalsbevinding, vermoeden bij 1 op 2000 MRI-onderzoeken [Morris 2009²²²]. Er bestaat geen vergelijkend onderzoek tussen vroege en late behandeling bij patiënten met een laaggradig glioom als toevalsbevinding. Voorstanders van een vroege resectie argumenteren dat de voordelen van resectie van een laaggradig glioom in een zeer vroeg stadium groter kunnen zijn, omdat de tumor nog kleiner is en completer operatief te verwijderen, terwijl de morbiditeit lager kan zijn [Kelly 2010¹⁶⁸; Pallud 2010²⁴⁷;

Duffau 2012⁸⁵; Potts 2012²⁶³]. Voorstanders van een late behandeling argumenteren dat de nadelen van een resectie veilig uitgesteld kunnen worden als MRI-follow-up plaatsvindt [Shah 2011³⁰⁷].

Er bestaat geen vergelijkend onderzoek voor een resectie met een ruime marge van niet-MRI-afwijkend weefsel, een zogenaamde supratotale resectie. Voorstanders van een supratotale resectie argumenteren dat een supratotale resectie waarschijnlijk een groter deel van de infiltrerende glioomcellen kan verwijderen mits uitgevoerd met intraoperatieve stimulatie mapping voor hersenfuncties [Yordanova 2011⁴⁰²].

In de meerderheid van bovengenoemde studies wordt een betere overleving bij resectie gemeld dan bij de 'watchful waiting' benadering. Dit behoeft enige nuancering. Alle genoemde artikelen zijn retrospectief van aard of betreffen cohortstudies en kunnen dus geen uitsluitsel geven over welke benadering superieur is.

Prospectief gerandomiseerde studies zullen zeer waarschijnlijk niet snel uitgevoerd worden vanwege ethische bezwaren. De belangrijkste problemen in de genoemde studies zijn de selectie bias en de eerder genoemde sampling error bij biopsie en beeldvorming bij een vermoedelijk laaggradig gliom. Zeer waarschijnlijk spelen de publicatiebias en conformation bias ook een rol, maar deze worden nu buiten beschouwing gelaten.

Hoewel een aantal studies corrigeert voor pathologische, klinische en radiologische karakteristieken in de multivariate analyse, kan niet worden uitgesloten dat onbekende factoren een rol kunnen spelen bij de selectie door de chirurg om te kiezen voor een radicalere benadering in plaats van watchful waiting. Een voorbeeld is de delineatie van de tumor op MRI. Hier wordt in geen van de genoemde artikelen voor gecorrigeerd. Een tumor met scherpe delineatie op MRI is over het algemeen makkelijker en 'radicaler' te opereren, maar heeft ook een betere prognose dan een infiltrerend laaggradig astrocytoom volgens sommigen [Ius 2012¹⁴⁵], terwijl andere auteurs dit weerspreken [Chang 2008⁵⁰]. Hoe scherper de delineatie op MRI, hoe eerder een chirurg zou kunnen beslissen om te opereren. De betere overleving kan zo gemakkelijk gerelateerd worden aan chirurgie, terwijl patiënten met een dergelijke tumor in feite al op voorhand een betere prognose hebben.

De keuze voor een behandeling kan afhankelijk zijn van veel factoren (zie aanbeveling). Belangrijk is om de patiënt goed te informeren over de voor- en nadelen van de verschillende behandelopties. Vooralsnog blijkt uit de literatuur niet dat een watchful waiting behandeling nadelig is voor geselecteerde patiënten met een laaggradig gliom [Whittle 2010³⁸⁵]. De benadering van Whittle kan misschien dienen als voorbeeld, waarbij het uitgangspunt is dat de patiënt zich comfortabel moet voelen met zijn of haar keuze voor een behandelstrategie, en dat het behandelteam dit beter vanuit een zekere flexibiliteit kan benaderen dan vanuit dogma.

Minimale mate van resectie bij laaggradig glioom

Uitgangsvraag

Wat is de minimale mate van resectie die zinvol is bij een patiënt met een laaggradig glioom?

Aanbeveling

Er is geen minimale mate van resectie aan te geven die zinvol is bij de indicatiestelling voor een operatie bij een patiënt met een vermoedelijk laaggradig glioom. Er zijn aanwijzingen dat een grotere mate van resectie zinvol kan zijn, maar er is geen minimaal zinvol percentage tumorverwijdering aan te geven en de betrouwbaarheid van de preoperatieve inschatting van de mate van resectie door de neurochirurg is onzeker.

In het geval een resectie wordt uitgevoerd, is het meten van de mate van resttumor en de mate van tumorverwijdering met behulp van pre- en postoperatieve MRI (flairopnames) te overwegen (zie module Beeldvormende diagnostiek).

Overwegingen

Omdat de mate van resectie alleen na een operatie vastgesteld kan worden en niet voorafgaand of tijdens een operatie, is de uitgangsvraag ook in de toekomst niet te beantwoorden met een gerandomiseerde studieopzet. Een grote of kleine mate van resectie kan niet tussen patiënten worden gerandomiseerd.

Bij de interpretatie van bovengenoemde studies is het evenwel een gegeven dat resultaten retrospectief zijn en sterk beïnvloed kunnen zijn door selectiebias. Fittere patiënten ondergaan immers de meer uitgebreide resecties, maar omdat gerandomiseerde data ontbreken kan geen uitspraak worden gedaan of de goede performance vooraf óf de mate van resectie de belangrijkste parameter voor langere overleving is.

In de besproken literatuur werden verschillende methodes gebruikt om het resectiepercentage van de tumor te meten. Tegenwoordig is volumetrie met flairopnames gebruikelijk, maar nog niet gestandaardiseerd. Studies waarin gebruik gemaakt wordt van de impressie van de chirurg als mate van resectie via operatieverslagen zijn onvoldoende betrouwbaar [Orringer 2012²⁴¹].

De patiënten die in deze publicaties werden beschreven zijn geselecteerd op basis van de histopathologische gradering die pas dagen na een operatie bekend is. Voor patiënten waarbij een inschatting gedaan wordt over de minimale mate van resectie voorafgaand aan een operatie staat in de klinische praktijk (nog) niet vast dat het daadwerkelijk een laaggradig glioom betreft. Wellicht verschilt de minimale mate van resectie bij een anaplastisch glioom van een laaggradig glioom.

Het is niet bekend in hoeverre de preoperatieve schatting van mate van resectie correspondeert met de behaalde mate van resectie voor deze patiënten. Zodoende is de waarde hiervan voor het selecteren van patiënten voor een 'zinvolle' resectie onduidelijk.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat een grotere mate van resectie bij een laaggradig glioom gepaard gaat met een

langere overleving en langere tijd tot progressie.

Pallud 2014²⁴⁴, Youland 2013⁴⁰⁴, Capelle 2013⁴³, Ius 2012¹⁴⁵, Schomas 2009³⁰¹, McGirth 2008²¹⁴, Smith 2008³¹⁹

Er zijn aanwijzingen dat bij een laaggradig glioom een langere overleving wordt behaald bij een minimaal percentage tumorverwijdering van respectievelijk 40%, 50%, 70%, 90%, of 100%; of als alternatieve mate van resectie uit een maximaal restvolume van nul mL, 10 mL, 15 mL, of 30 mL. Er is dus geen eenduidige minimale mate van resectie die de overleving verlengt.

Smith 2008³¹⁹, Capelle 2013⁴³, Ius 2012¹⁴⁵, Youland 2013⁴⁰⁴, Schomas 2009³⁰¹, McGirth 2008²¹⁴, Pallud 2014²⁴⁴

Samenvatting literatuur

In de literatuur werd geen publicatie gevonden die deze uitgangsvraag als onderzoeksvorag direct beantwoordt. In vergelijkend onderzoek in cohorten van patiënten die een operatie ondergingen voor een laaggradig glioom werd de mate van resectie weergegeven als percentage verwijderd tumorvolume of als restvolume. Deze parameters werden verschillend gecategoriseerd zonder dat duidelijk wordt op welke gronden deze categorieën tot stand kwamen.

Hiernavolgend worden de publicaties besproken die (a) meer dan 100 patiënten na operatie voor laaggradig glioom beschreven, (b) de mate van resectie baseerden op MRI-metingen, en (c) na 2000 werden gepubliceerd.

In zeven retrospectieve chirurgische series werd een significante associatie vastgesteld tussen overleving en uitgebreidere mate van resectie, waarbij de mate van resectie soms gekwantificeerd werd als percentage tumorverwijdering, soms als rest tumorvolume in mL.

Pallud [Pallud 2014²⁴⁴] beschreef 1509 patiënten tussen 1992 en 2011, waarvan 890 een resectie ondergingen en 619 een biopsie. Pre- en postoperatieve tumorvolumes werden gemeten op de flair- opnames van de MRI. Partiële resectie werd gedefinieerd als een restvolume ≥ 10 mL (427 patiënten), subtotal resectie als een restvolume < 10 mL maar > 0 mL (313 patiënten), en een totale resectie als afwezigheid van restvolume (150 patiënten) op de MRI. Ten opzichte van de subgroep met biopsie of partiële resectie was de overleving langer bij totale resectie (HR: 0,51; 95%CI 0,30-0,88; p = 0,016) en bij subtotal resectie (HR: 0,81; 95%CI 0,59-1,10; P = 0,169). De tijd tot overlijden of maligne transformatie was langer na totale resectie (HR: 0,22; 95%CI 0,16-0,32; p <0,001) en na subtotal resectie (HR: 0,43; 95%CI 0,35-0,53; p <0,001) ten opzichte van de subgroep na biopsie of partiële resectie.

Youland [Youland 2013⁴⁰⁴] beschreef 852 patiënten tussen 1960 en 2011, waarvan een subgroep van 517 patiënten werd behandeld tussen 1990 en 2011, waarbij 349 patiënten een resectie ondergingen en 222 patiënten een biopsie. De mate van resectie werd bepaald door pre- en postoperatieve beeldvorming te vergelijken of, indien dit niet beschikbaar was, via de operatieverslagen. Totale resectie werd gedefinieerd als afwezigheid van resttumor op MRI (176 patiënten), radicale subtotal resectie als een verwijderd volume van > 90% (55 patiënten), en subtotal resectie als een verwijderd volume van < 90% (118 patiënten). Na totale of radicale subtotal resectie leefden patiënten langer ten opzichte van de subgroep met biopsie of subtotal

resectie (gecorrigeerde risico ratio: 0,61; 95%CI 0,43-0,86; p = 0,004). Na totale of radicale subtotalresectie was de tijd tot progressie langer dan in de subgroep na biopsie of subtotalresectie (gecorrigeerde risico ratio: 0,45; 95%CI 0,35-0,59; p < 0,001).

Capelle [Capelle 2013⁴³] beschreef 1091 patiënten die behandeld werden tussen 1985 en 2007, waarvan 674 een resectie ondergingen, 619 een biopsie, en bij 165 behandeling werd uitgesteld. Pre- en postoperatieve tumorvolumes werden gemeten op T1-, T2- en flairoppnames. Er werd onderscheid gemaakt in het percentage tumor dat verwijderd was. Bij 80 patiënten was de tumor voor 100% verwijderd, bij 418 patiënten was tussen 50 en 99% van de tumor verwijderd en bij 431 patiënten was minder dan 50% verwijderd. Complete resectie werd gedefinieerd als geen restvolume op MRI (80 patiënten), subtotalresectie als een restvolume <10 mL en > 0 mL (266 patiënten), een partiële resectie als een restvolume >10 mL (583 patiënten). Het percentage tumorverwijdering als continue parameter was geassocieerd met een gunstiger overleving (gecorrigeerde relatieve risico: 0,569; 95%CI 0,382-0,847; p = 0,0199). De overlevingscurves van complete, subtotalresectie, en partiële resectie lopen uiteen tot 14 jaar follow-up zonder dat hiervoor statistische significantie werd berekend.

Ius [Ius 2012¹⁴⁵] beschreef 190 patiënten die behandeld werden tussen 1998 en 2011, en die een resectie ondergingen van een laaggradig glioom in een eloquente lokalisatie. De mate van resectie werd bepaald door pre- en postoperatieve volumetingen op T2-gewogen MRI-opnames. Dit werd gemeten als percentage tumorverwijdering en als volume resttumor. Zo werd bij 30 patiënten minder dan 70% tumor verwijderd, bij 69 werd tussen 70 en 89% en bij 91 werd meer dan 90%. Bij 11 patiënten bestond een tumor restvolume van minder dan 10mL, bij 41 patiënten tussen 11 en 20 mL, bij 16 patiënten tussen 21 en 30 mL en bij 22 patiënten meer dan 31mL. Patiënten met een percentage tumorverwijdering tussen 70 en 89% leefden korter dan patiënten met meer dan 90% tumorverwijdering (HR: 4,85; 95%CI 1,79-13,1; p = 0,002). Ook patiënten met minder dan 70% tumorverwijdering leefden korter dan patiënten met meer dan 90% tumorverwijdering (HR: 19,7; 95%CI 7,01-54,8; p < 0,0001). Een hoger percentage tumorverwijdering als continue parameter was significant geassocieerd met langere overleving (HR per procent: 0,933; 95%CI 0,915-0,952; p < 0,0001). Bij patiënten met een rest tumorvolume van minder dan 10 mL was de overleving langer dan bij een rest tumorvolume tussen 11 en 20 mL (HR: 3,28; 95%CI 1,34-8,04; p = 0,009), bij een rest tumorvolume tussen 21 en 30 mL (HR: 6,50; 95%CI 2,43-17,4; P < 0,0001), en bij een rest tumorvolume meer dan 30 mL (HR: 14,0; 95%CI 5,68-34,4; p < 0,0001). Een kleiner rest tumorvolume als continue parameter was geassocieerd met een langere overleving (HR per mL tumorrest: 1,02; 95%CI 1,01-1,03; P < 0,0001). Ten opzichte van de patiënten met meer dan 90% tumorverwijdering hadden de patiënten met tussen 70 en 89% tumorverwijdering kortere tijd tot maligne transformatie (HR: 2,55 (95%CI 1,35-4,84; p = 0,004), evenals de patiënten met minder dan 70% tumorverwijdering (HR: 9,77; 95%CI 4,85-19,7; p < 0,0001). Meer tumorverwijdering per procent was geassocieerd met kortere tijd tot maligne transformatie (HR: 0,944; 95%CI 0,928-0,960; p < 0,0001). Ten opzichte van de patiënten met een rest tumorvolume van minder dan 10 mL was de tijd tot maligne transformatie korter voor patiënten met een rest tumorvolume tussen 11 en 20 mL (HR: 1,54; 95%CI 0,80-2,97; p = 0,20), evenals voor patiënten met een rest tumorvolume tussen 21 en 30 mL (HR: 2,98; 95%CI 1,37-6,50; p = 0,006), evenals voor patiënten met een rest tumorvolume van meer dan 31 mL (HR: 8,74; 95%CI 4,41-17,3; p < 0,0001). Meer tumorrest per mL was geassocieerd met een kortere tijd tot maligne transformatie (HR: 1,02; 95%CI 1,01-1,03; P < 0,0001).

Schomas [Schomas 2009³⁰¹] beschreef 314 patiënten tussen 1960 en 1992, waarvan 204 een resectie ondergingen en 110 een biopsie. De mate van resectie werd bepaald door het operatieverslag, de impressie van de chirurg en postoperatieve beeldvorming, indien aanwezig. Totale resectie werd gedefinieerd als afwezigheid van resttumor (41 patiënten), radicale subtotalresectie als een verwijderd volume van meer dan 90% (33 patiënten), en subtotalresectie als een verwijderd volume van minder dan 90% (130 patiënten). Patiënten leefden na biopsie of subtotalresectie korter dan patiënten na totale of radicale subtotalresectie (gecorrigeerde relatieve risico: 0,74; 95%CI 0,55-0,96; P < 0,001).

McGirth [McGirth 2008²¹⁴] beschreef 170 patiënten die tussen 1996 en 2007 een resectie ondergingen. De mate van resectie werd door de radioloog bepaald op pre- en postoperatieve flairoopnames van de MRI. Als 'gross total resection' werd gedefinieerd de afwezigheid van resttumor (65 patiënten), als 'near total resection' een rest met een dikte minder dan 3 mm rond de resectieholte (39 patiënten), en als subtotalresectie een nodulaire resttumor (66 patiënten). Ten opzichte van de patiënten met een subtotalresectie leefden patiënten na een 'gross total resection' langer (gecorrigeerde HR: 0,36; 95%CI 0,16-0,84; p = 0,017), evenals na een 'near total resection' (gecorrigeerde HR: 0,87; 95%CI 0,38-1,98; p = 0,63). Ten opzichte van de patiënten na een subtotalresectie was de tijd tot progressie langer na 'gross total resection' (gecorrigeerde HR: 0,56; 95%CI 0,32-0,98; p = 0,043) evenals na 'near total resection' (gecorrigeerde HR: 1,01; 95%CI 0,69-1,99; p = 0,75).

Smith [Smith 2008³¹⁹] beschreef 216 patiënten, behandeld tussen 1989 en 2005, die een resectie ondergingen. Pre- en postoperatieve tumorvolumes werden gemeten op de flairoopnames van de MRI. De mate van resectie werd berekend als percentage tumorverwijdering op MRI. Bij 21 patiënten werd een resectie met 0 tot 40% tumorverwijdering uitgevoerd, bij 94 patiënten met 41 tot 89%, bij 26 patiënten met 90 tot 99% en bij 75 patiënten met 100%. Daarnaast werd het tumor- restvolume berekend. Bij 75 patiënten resteerde 0 mL tumor, bij 37 patiënten tussen 1 en 5 mL, en bij 38 patiënten tussen 5,1 en 15mL. Een hogere mate van tumorverwijdering als percentage was geassocieerd met een langere overleving (gecorrigeerde HR per procent: 0,972; 95%CI 0,960-0,983; p <0,001) en een langere tijd tot maligne transformatie (gecorrigeerde HR per procent: 0,983; 95%CI 0,972-0,995; p = 0,005). Een kleinere mate van resttumor in mL was eveneens geassocieerd met een langere overleving (gecorrigeerde HR per mL: 1,010; 95%CI 1,001-1,019; p = 0,03) en een lange tijd tot maligne transformatie (HR: 1,005; 95%CI 0,996-1,014; p = 0,32).

Behandeling bij nieuw gediagnosticeerd laaggradig glioom

Uitgangsvraag

Welke patiënten met een laaggradig glioom komen in aanmerking voor een vervolgbehandeling na operatie?

De zoekvraag omvat de volgende deelvragen:

- Wat is het effect van chemotherapie bij patiënten met een laaggradig glioom?
- Wat is het effect van radiotherapie bij patiënten met een laaggradig glioom?
- Wat is het effect van chemotherapie en radiotherapie bij patiënten met een laaggradig glioom?

Aanbeveling

Bespreek een 'wait and scan' beleid met de patiënt indien er geen negatieve prognostische factorer¹ zijn EN er sprake is van een radicale resectie.

Geef radiotherapie gevolgd door chemotherapie bij:

- minstens twee negatieve prognostische factoren¹ waarbij een grote rest tumor en/of farmacoresistente epilepsie postoperatief ook als negatieve prognostische factoren gelden;
- patiënten bij wie om andere redenen de indicatie voor nabehandeling gesteld is.

Geef radiotherapie 50,4 Gy bij patiënten met een laaggradig glioom zonder moleculaire hooggradige kenmerken. Het is niet aangetoond dat meer dan 50,4 Gy de overleving verbetert.

Geef bij voorkeur bij tumoren met 1p/19q-codeletie zes kuren PCV-combinatietherapie en bij tumoren zonder 1p/19q-codeletie bij voorkeur 12 kuren temozolomide monotherapie.

Beschouw tumoren met een IDHwt en met moleculaire kenmerken van een glioblastoom als een glioblastoom.

Pas shared decision making toe waarbij de te verwachten effecten en voor- en nadelen van de verschillende behandelopties met de patiënt besproken worden.

Bespreek dat sequentiele radio- en chemotherapie de gemiddelde overleving verlengt, maar dat een langere overleving de kans op cognitieve verslechtering vergroot

¹ Zie module 'Klinisch prognostische factoren laaggradig glioom.'

Overwegingen

In de nieuwste WHO-classificatie speelt moleculaire diagnostiek een grote rol, echter studies gepubliceerd voor 2016 hielden daar geen rekening mee (Louis, 2016) (zie module Diagnostiek - neuropathologie - typering/gradering diffuse gliomen). Bij een glioom die pathologisch gegradeerd wordt als een laaggradig

glioom heeft de afwezigheid van een IDH-mutatie een slechte prognose. In combinatie met een EGFR-amplificatie, +7/-10-mutatie en/of aanwezigheid van een TERT-promotormutatie kan de tumor worden gekarakteriseerd als glioblastoom (zie module Diagnostiek - neuropathologie - typering/gradering diffuse gliomen).

Alle gerandomiseerde studies geïncludeerd in de literatuursamenvatting zijn van toepassing op supratentoriële laaggradige gliomen. Er kunnen dus geen uitspraken gedaan worden over infratentoriële of ruggenmerggliomen.

Voorts ontbreekt een controlegroep zonder behandeling in de studies vanwege ethische overwegingen. Het natuurlijk beloop van laaggradige gliomen kennen we daarom niet.

Als er geen negatieve prognostische factoren zijn (zie module Klinisch prognostische factoren laaggradig glioom) EN er sprake is van een radicale resectie, dan kan er een afwachtend beleid volgen.

Chemotherapie

Vanwege de lage bewijskracht van de studie van Baumert (2016) kan geen harde uitspraak over het tijdstip van inzetten van aanvullende behandeling gedaan worden, al wordt wel een periode van maximaal twaalf weken tussen chirurgie en de aanvang van chemotherapie aanbevolen.

Radiotherapie

Alhoewel de EORTC-22854-studie kwaliteit van leven niet analyseerde, werd een significant lagere frequentie van epilepsie na één jaar gezien in de groep patiënten die postoperatieve radiotherapie kreeg (25%) ten opzichte van de groep met uitgestelde radiotherapie (41%) ($p=0,0329$), waardoor bij geselecteerde patiënten met onbehandeld laaggradig glioom en moeilijk behandelbare epilepsie te overwegen valt om eerder te bestralen (van den Bent, 2005).

Twee studies die niet in de literatuursamenvatting zijn meegenomen omdat deze de uitgangsvraag niet beantwoordden, maar wel de effecten op cognitie na radiotherapie onderzochten, zijn Brown (2003) en Douw (2009). Brown (2003) vond bij 203 volwassen patiënten, gerandomiseerd in twee groepen met lage of hoge dosis radiotherapie, geen onderling verschil in MMSE-scores in 7,4 jaar follow-up. In beide groepen werd wel een significante verbetering in cognitie gezien ten opzichte van de baselinemeting. Douw (2009) heeft in een cohortstudie met een follow-up van twaalf jaar cognitie gemeten door middel van uitgebreide testen bij patiënten met een laaggradig glioom behandeld met of zonder radiotherapie. Terwijl er zes jaar na diagnose geen verschil in cognitie te zien was, bleek de concentratie beduidend verminderd te zijn twaalf jaar na radiotherapie. Overigens zijn deze resultaten mogelijk gebiased doordat patiënten met progressieve ziekte werden geëxcludeerd. Daarom is het aan te raden om prognostische factoren (zie module Klinisch prognostische factoren laaggradig glioom) door de behandelaar mee te laten wegen bij het al dan niet vroegtijdig starten van radiotherapie (Pignatti, 2002; Douw, 2009; van den Bent, 2012; Shields, 2014).

Aanvullend is een Pubmed search op de termen "cognitive effects" en "neurocognition" in combinatie met "low grade glioma" verricht. Hieruit kwamen 83 titels waarvan de meeste niet standaard therapie-effect op neurocognitie onderzochten. Uiteindelijk werden 14 titels nader onderzocht op abstract waarbij opnieuw een

aantal afvielen wegens pediatrische studie, enkel MMSE of niet gericht op effect van chemo- of radiotherapie. Naast drie artikels uitgezocht op full tekst werd een artikel van Klein (2012) toegevoegd.

Correa (2007) onderzocht neurocognitief effect van radiotherapie en chemotherapie versus "wait-and-scan beleid" bij 41 patiënten met een laaggradige glioom door middel van een uitgebreid gestandaardiseerd neuropsychologische testpanel. Er mocht geen tumorprogressie tijdens follow-up zijn ontstaan bij een mediane therapie interval van 3 jaar ten opzichte van testafname. Ondanks de kleine aantallen bleek de behandelde groep significant lagere neurocognitieve scores te hebben ten opzichte van de onbehandelde groep. Deze effecten bleken meer uitgesproken indien de behandeling langer geleden was dan 3 jaar.

Laack (2005) onderzocht neurocognitief effect van radiotherapie door middel van uitgebreide testbatterij naast MMSE bij twintig patiënten met een laaggradig glioom. Metingen werden vooraf de bestraling en vervolgens elke 18 maanden tot max 5 jaar na bestraling verricht. Er werd geen effect gezien in dosering van bestraling tussen een groep met 50,4 Gy of 64,8 Gy. Hierbij dient bemerkt te worden dat dit om kleine aantallen gaat.

Klein (2002) onderzocht neurocognitie in een veel grotere groep patiënten (n=195) met follow-up van 1 tot 22 jaar na bestraling van een laaggradig glioom. Ook in deze studie werden meerdere neuropsychologische domeinen onderzocht middels testbatterijen. Ook hier werd leek bestraling een negatief effect op neurocognitie te hebben echter het effect van de tumor zelf en het gebruik van anti-epileptica hadden een groter effect op cognitie dan radiotherapie. In een vervolgstudie met langere follow-up van gemiddeld 12 jaar (n=65), echter, laat de helft van de bestraalde patiënten een achteruitgang zien van aandachtsfuncties in vergelijking met 27% in de onbehandelde groep. Concluderend lijken er aanwijzingen te zijn dat radiotherapie op lange termijn de cognitie (met name aandacht) negatief beïnvloedt.

Een bestralingsdosis van 50 tot 54 Gy in fracties van 1,8 Gy wordt wereldwijd het meest gebruikt en geadviseerd bij de behandeling van patiënten met een laaggradig glioom. Indien de beslissing, in overleg met de patiënt, genomen is om te bestralen, heeft het de voorkeur om sequentieel chemokuren toe te dienen (op basis van CATNON- en NOA-04-studies), tenzij er specifieke contra-indicaties of wensen van de patiënt zijn om dit niet te doen (Wick, 2009; van den Bent, 2017).

De radiotherapie en beeldvorming technieken hebben over de tijd een grote evolutie doorgemaakt, waardoor het radiotherapie doelvolume nauwkeuriger kan worden bepaald en behandeld. De uitkomsten op cognitie van de besproken studies zijn verkregen met radiotherapie technieken die niet representatief zijn voor de huidige praktijk.

De definitie van het radiotherapie-doelvolume is gebaseerd op een recente MRI (Kwaliteitscriteria neuro-oncologie 2017). Het te bestralen gebied omvat het hyper intense gebied op de T2- of FLAIR-sequenties met een beperkte marge voor microscopische ziekte. Het gebruik van geavanceerde radiotherapietechnieken zijn de norm (Werkafspraken volgens Landelijk Platform Neuro-oncologie van de NVRO).

Chemotherapie en radiotherapie

De studie van Buckner (2016) liet zien dat patiënten met IDHmut tumoren een langere progressievrije

overleving hebben ten opzichte van IDHwt tumoren, ongeacht de behandelarm (echter was de subgroep met IDHwt te klein voor een statistische analyse). Gunstige prognostische factoren zijn: behandeld met chemotherapie gecombineerd met radiotherapie, oligodendroglioom als histologie en leeftijd jonger dan 40 jaar. De overall survival (OS) was superieur voor de gecombineerde therapie voor alle histologische groepen, al was het verschil voor de astrocytoma groep niet significant. De beperkte data die er zijn lieten geen afname in kwaliteit van leven of cognitie zien door toevoeging van PCV-kuren aan radiotherapie (Prabhu, 2014; Habets, 2014). Daarom wordt aangeraden dat de behandelaar altijd de gecombineerde behandeling in overweging neemt.

Studies die temozolamide in plaats van PCV bij patiënten met laaggradige gliomen onderzoeken, ontbreken. Bij de anaplastische gliomen werd echter in de gerandomiseerde fase III NOA-04-studie geen verschil aangetoond in progressievrije overleving tussen PCV en temozolamide, maar de studie was hier ook niet voor gepowered (Wick, 2009) (zie ook module Chemotherapie nieuw gediagnosticeerd anaplastisch glioom). De CATNON-studie vergelijkt postoperatieve bestraling met en zonder temozolamide (van den Bent, 2017). De interimresultaten van deze studie bij 745 patiënten met nieuw gediagnostiseerde anaplastische gliomen laat zien dat de HR voor OS 0,65 (95%BI: 0,45-0,93) was. De OS na vijf jaar was 55,9% (95%BI: 47,2- tot 63,8) vergeleken met 44,1% (36,3-51,6) bij respectievelijk met en zonder temozolamide. In analogie zou hierdoor dus ook bij laaggradige gliomen de toevoeging van twaalf kuren temozolamide na bestraling overwogen kunnen worden in plaats van zes PCV-kuren (Wick, 2009; van den Bent, 2017).

Shared decision making

In alle gevallen dient er sprake te zijn van shared decision making waarbij de te verwachten effecten en voor- en nadelen van de verschillende behandelopties met de patiënt besproken worden.

Onderbouwing

Achtergrond

De behandeling van patiënten met een laaggradig glioom blijft een controversieel onderwerp. Door recente ontwikkelingen in de moleculaire diagnostiek, de kennis over de diagnostische, prognostische en predictieve waarde hiervan is er meer kennis over welke patiëntengroep welke behandeling (radiotherapie, chemotherapie of beide) zou moeten krijgen. Het is van belang deze patiëntengroep te definiëren.

Conclusies

Chemotherapie

Laag GRADE	<p>Progressievrije overleving</p> <p>Er is mogelijk een klinisch relevant verschil in progressievrije overleving tussen alleen chemotherapie versus alleen radiotherapie in het voordeel van alleen radiotherapie bij patiënten met een laaggradig glioom. Dit verschil is mogelijk meer uitgesproken bij patiënten zonder gecombineerd verlies van 1p en 19q.</p> <p><i>Bronnen: (Baumert, 2016)</i></p>

Samenvatting literatuur

Eén van de dertien geïncludeerde artikelen bleek een systematische review die het effect van chemotherapie na operatie beschrijft bij patiënten met een laaggradig glioom (Ziu, 2015). Omdat deze review maar één RCT (Shaw, 2012) includeerde die ook afzonderlijk is geïncludeerd, is ervoor gekozen deze RCT afzonderlijk te beschrijven en de review van Ziu alsnog te excluderen. Er zijn dus 12 artikelen opgenomen in de literatuuranalyse die beschreven wat het effect is van chemotherapie, radiotherapie, of chemo- en radiotherapie na operatie bij volwassen patiënten met een laaggradig glioom op algehele overleving, progressievrije overleving, kwaliteit van leven en/of cognitie. Het gaat om twee systematische literatuurreviews en tien RCT's. In enkele studies werden de resultaten uit eenzelfde trial gebruikt om verschillende vragen te beantwoorden. De belangrijkste studiekarakteristieken en resultaten van de 12 artikelen zijn opgenomen in de evidencetabellen. De beoordeling van de individuele studieopzet (risk of bias) is opgenomen in de risk of biastabellen.

Chemotherapie

Baumert (2016) en Reijneveld (2016) vergeleken het effect van chemotherapie (dose-dense temozolamide) met radiotherapie voor de uitkomstmaten algehele overleving en progressievrije overleving (Baumert, 2016) en kwaliteit van leven en cognitief functioneren (Reijneveld, 2016). Beiden beschreven de resultaten van de EORTC-22033-26033-studie. In deze studie werden 477 volwassen patiënten met diffuus astrocytoom (WHO-graad II), oligodendroglioom of gemengd oligoastrocytoom met een WHO-performance score van 2 of lager, gerandomiseerd in een groep die radiotherapie kreeg ($n=237$) en een groep die chemotherapie kreeg ($n=240$).

Progressievrije overleving

De progressievrije overleving was voor dose-dense temozolamide 39 maanden (95%BI: 35 tot 44) ($n=237$) en voor radiotherapie 46 maanden (95%BI: 40 tot 56) ($n=240$), hazard ratio (HR) 1,16 (95%BI: 0,9 tot 1,5, $p=0,22$). Aanvullend bleek uit exploratieve analyse dat dit verschil in progressievrije overleving meer uitgesproken was in de groep patiënten met gemuteerd IDH maar zonder verlies van 1p/19q (radiotherapie: 55 maanden (95% BI:47-66); chemotherapie 36 maanden (95%BI: 28-47) ($n=165$) HR 1,86 (95%BI: 1,21 tot ,87).

Algehele overleving

Hoewel Baumert (2016) algehele overleving als secundair eindpunt had gedefinieerd, werd bij de mediane follow-up van 48 maanden de mediane algehele overleving niet bereikt in zowel de radiotherapiegroep als in de chemotherapiegroep.

Kwaliteit van leven

Reijneveld (2016) vergeleek de verschillen in aan gezondheid gerelateerde kwaliteit van leven (HRQoL) tussen patiënten behandeld met radiotherapie en met chemotherapie. Het verschil in HRQoL tussen de twee behandelgroepen was niet significant gedurende 36 maanden follow-up (gemiddeld over alle tijdstippen: 0,06, 95%BI: -4,64 tot 4,75, p=0,98). In beide groepen bleven de gemiddelde algehele gezondheid en de kwaliteit van leven stabiel door de tijd.

Cognitie

Reijneveld (2016) vergeleek cognitie tussen patiënten behandeld met radiotherapie en patiënten behandeld met chemotherapie gedurende een follow-up van drie jaar. Op baseline hadden 32 (13%) van de 239 patiënten die radiotherapie kregen en 32 (14%) van de 236 patiënten die temozolamide-chemotherapie kregen een verminderde cognitieve functie volgens de Mini Mental State Examination-scores (MMSE). Na randomisatie hadden 5 (8%) van de 63 patiënten die radiotherapie kregen en 3 (6%) van de 54 patiënten die temozolamide-chemotherapie kregen, een verminderde cognitieve functie volgens MMSE-scores. Er werd geen significant verschil gevonden tussen de twee behandelgroepen.

Radiotherapie

Er zijn zeven studies gevonden die effecten van radiotherapie na operatie bij patiënten met een laaggradig glioom onderzochten, waaronder twee systematische reviews (Ryken, 2015; Sarmiento, 2015) en vijf RCT's (Karim, 1996; Kiebert, 1998; Karim, 2002; Shaw, 2002; van den Bent, 2005).

Systematische reviews

De systematische review van Ryken (2015) includeerde 142 studies waaronder zes RCT's (Eyre, 1993 (past niet binnen de uitgangsvraag); Karim, 1996; Kiebert, 1998; Karim, 2002; Shaw, 2002; van den Bent, 2005). Deze RCT's zijn allen apart geïncludeerd door de werkgroep en apart beschreven in deze module. De andere studies geïncludeerd in Ryken zijn van mindere methodologische kwaliteit en daarom wordt Ryken hier niet verder beschreven.

In de Cochrane review van Sarmiento (2015) werden de effecten van postoperatieve radiotherapie versus radiotherapie uitgesteld tot tumorprogressie na biopsie of chirurgische resectie onderzocht. Sarmiento (2015) includeerde slechts één studie: een multicenter RCT met patiënten met een laaggradig glioom (van den Bent, 2005; EORTC-22845). De patiënten werden gerandomiseerd in een postoperatieve radiotherapiegroep (n=157) of in de groep met uitgestelde radiotherapie tot het optreden van progressie (n=157). Voor het beschrijven van de studieresultaten wordt daarom gerefereerd aan van den Bent (2005).

RCT's

Karim (2002) beschreef de eerste resultaten van bovengenoemde EORTC-studie (van den Bent, 2005). Middels de RCT van Shaw (2002) werden de effecten van lage versus hoge dosis radiotherapie in 203 volwassenen met een supratentoriaal laaggradig glioom onderzocht. Karim (1996) onderzocht eveneens de effecten van lage versus hoge dosis radiotherapie in een RCT met 379 volwassenen met laaggradig glioom. Kiebert (1998) onderzocht in dezelfde RCT als Karim (1996) de kwaliteit van leven, gerapporteerd door patiënten zelf en door artsen, bij patiënten met laaggradig glioom welke een lage of een hoge dosis radiotherapie kregen.

Progressievrije overleving

Van den Bent (2005) liet zien dat postoperatieve radiotherapie geassocieerd is met een toename in tijd tot progressie van de ziekte in vergelijking tot observatie/afwachtend beleid (en uitgestelde radiotherapiebehandeling tot ziekteprogressie) voor mensen met een laaggradig glioom. De mediane progressievrije overleving was 5,3 jaar in de postoperatieve radiotherapiegroep en 3,4 jaar in de uitgestelde radiotherapiegroep (HR: 0,59, 95%BI: 0,45 tot 0,77; p<0,0001).

De studie van Shaw (2002) toonde geen significant verschil aan tussen een lage dosis (50,4 Gy, n=101) en hoge dosis radiotherapie (64,8 Gy, n=102) in de tijd tussen de start van behandeling en progressie van de ziekte (TTP) (log rank P = 0,65). De gemiddelde TTP was 5,5 jaar.

Ook de studie van Karim (1996) vond geen significante verschillen in progressievrije overleving tussen lage dosis (45 Gy, n=171) en hoge dosis radiotherapie (59,4 Gy, n=172). Het aantal overlevenden zonder progressie van ziekte na 5 jaar is 47% bij lage dosis radiotherapie en 50% bij hoge dosis radiotherapie.

Algehele overleving

De mediane algehele overleving in de groep die postoperatieve radiotherapie kreeg, was 7,4 jaar, terwijl de groep die late radiotherapie kreeg (bij ziekteprogressie) een mediane algehele overleving had van 7,2 jaar (HR 0,97, 95%BI: 0,71-1,33; p= 0,872). Dit verschil was niet significant (van den Bent, 2005).

De studie van Shaw (2002) vond geen significant verschil tussen lage (50,4 Gy) en hoge (64,8 Gy) dosis radiotherapie in algehele overleving (log rank P = 0,48). De 2- en 5-jaars overleving waren iets beter in de lage dosis radiotherapie. De mediane overleving was 9,25 jaar.

De studie van Karim (1996) vond ook geen significante verschillen in algehele overleving tussen lage dosis (45 Gy) en hoge dosis (59,4 Gy) radiotherapie.

Kwaliteit van leven

De studie van Kiebert (1998) onderzocht de door patiënten zelf gerapporteerde kwaliteit van leven na lage dosis radiotherapie (45 Gy) en na hoge dosis radiotherapie (59,4 Gy). Direct na bestraling rapporteerden de patiënten in de hoge dosisgroep lagere niveaus in functioneren en meer klachten dan de patiënten in de lage dosisgroep. Deze verschillen waren significant voor vermoeidheid/malaise ($p=0,03$) en slapeloosheid ($p=0,05$). Na 7 tot 15 maanden na randomisatie scoorde de hoge dosisgroep significant slechter op vrijetijdsbesteding ($p=0,01$) en emotioneel functioneren ($p=0,01$) dan de lage dosisgroep. Er waren geen verschillen in de verschillende aspecten van kwaliteit van leven in beide groepen voor en na behandeling.

Cognitie

Er zijn geen studies geïncludeerd die voldoen aan de selectiecriteria en cognitie beschreven bij radiotherapie.

Chemo- en radiotherapie

Er zijn drie RCT's die de effecten van chemo- en radiotherapie na operatie bij patiënten met een laaggradig glioom onderzochten (Shaw, 2012; Prabhu, 2014; Buckner 2016). Shaw (2012) beschrijft de eerste resultaten van de RTOG-9802 studie van Buckner (2016) en is daarom niet apart beschreven. Prabhu (2014) onderzocht

het effect van additionele chemotherapie bij radiotherapie op cognitief functioneren (MMSE-scores) in vergelijking tot alleen radiotherapie bij 251 patiënten met een laaggradig glioom. Hiervoor zijn resultaten van de RTOG-9802-studie geanalyseerd. Buckner (2016) beschreef de lange termijneffecten van behandeling met procarbazine, lomustine en vincristine na radiotherapie bij 251 patiënten met een astrocytoom, oligoastrocytoom of oligodendrogloom, in vergelijking met enkel radiotherapie. Patiënten werden geïncludeerd indien jonger dan 40 jaar met subtotal resectie of biopsie; of ouder dan 40 jaar met elke vorm van resectie of biopsie.

Progressievrije overleving

Buckner (2016) vond een significant verschil in progressievrije overleving tussen 125 patiënten behandeld met radiotherapie gevolgd door chemotherapie (PCV-kuren) (gemiddelde progressievrije overleving: 10,4 jaar, 95%BI: 6,1-niet behaald) en 126 patiënten met alleen radiotherapie als behandeling (gemiddelde progressievrije overleving: 4,0 jaar, 95%BI: 3,1-5,5) (HR voor ziekteprogressie of sterfte: 0,50; $p<0,001$). Het verschil in progressievrije overleving werd pas zichtbaar nadat 25% van de patiënten ziekteprogressie had en het verschil nam toe gedurende de tijd.

Algehele overleving

Buckner (2016) beschreef bij patiënten met gecombineerde behandeling een langere mediane algehele overleving dan bij patiënten met alleen radiotherapie (13,3 versus 7,8 jaar respectievelijk, HR voor overlijden: 0,59; $p=0,003$).

De algehele overleving na vijf jaar was 72% (95%BI: 64-80) in de groep die radiotherapie plus chemotherapie kreeg versus 63% (95%BI: 55-72) in de groep die alleen radiotherapie kreeg. Deze percentages waren na 10 jaar 60% (95%BI: 51-69) en 40% (95%BI: 31-49) respectievelijk.

Kwaliteit van leven

De uitkomstmaat kwaliteit van leven is niet beschreven in de geïncludeerde studies die chemo- en radiotherapie onderzochten.

Cognitie

In de RTOG-9802 studie heeft Prabhu (2014) gedurende vijf jaar een MMSE-score afgenoemt. Het toevoegen van chemotherapie (PCV) aan radiotherapie gaf geen significant grotere afname in MMSE-scores dan alleen radiotherapie gedurende vijf jaar follow-up. Beide groepen ervaarden een statistisch significante toename van de gemiddelde MMSE-score gedurende de tijd. Er was geen verschil tussen beide groepen ($P=0,57$).

Bewijskracht van de literatuur

Volgens de GRADE-beoordeling starten RCT's op een hoog niveau van bewijskracht.

Chemotherapie

De bewijskracht voor de uitkomstmaat progressievrije overleving is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (risk of bias, gebrek aan blinding van de beoordelaars MRI) en vanwege het overschrijden van de grens voor klinische relevantie (imprecisie). De bewijskracht voor algehele

overleving is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (risk of bias, mediane overleving niet bereikt, twee niveaus afgetrokken). De bewijskracht voor de uitkomstmaten kwaliteit van leven en cognitie is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (risk of bias, gebrek aan blinding) en het geringe aantal patiënten (imprecisie).

Radiotherapie

De bewijskracht voor de uitkomstmaat progressievrije overleving voor de vergelijking postoperatieve radiotherapie versus radiotherapie bij progressie is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (risk of bias, vanwege gebrek aan blinding) en imprecisie (doorkruisen van de grens voor klinische relevantie). De bewijskracht voor de uitkomstmaat progressievrije overleving voor de vergelijking lage versus hoge dosis radiotherapie is met één niveau verlaagd tot 'redelijk' gezien beperkingen in de onderzoeksopzet (risk of bias, vanwege gebrek aan blinding en onduidelijkheid in de manier van randomiseren). De bewijskracht voor de uitkomstmaat algehele overleving is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (geringe aantal patiënten en onduidelijkheid in de manier van randomiseren). De bewijskracht voor de uitkomstmaat kwaliteit van leven is met drie niveaus verlaagd gezien een aantal beperkingen in de onderzoeksopzet (risk of bias, waaronder gebrek aan blinding). Daarnaast wordt veel zaken in het artikel niet nader toegelicht, zoals manier van randomiseren en hoeveel patiënten er tijdens de studieduur zijn uitgevallen).

Chemo- en radiotherapie

De bewijskracht voor de uitkomstmaat progressievrije overleving en algehele overleving is met twee niveaus verlaagd tot 'laag' gezien beperkingen in de onderzoeksopzet (risk of bias, gebrek aan blinding/het geringe aantal patiënten). De bewijskracht voor de uitkomstmaat cognitie is met twee niveaus verlaagd gezien beperkingen in de onderzoeksopzet (risk of bias, gebrek aan blinding, relatief hoge loss-to-follow-up) en het geringe aantal patiënten (imprecisie).

Zoeken en selecteren

Om de uitgangsvraag te kunnen beantwoorden is er een systematische literatuuranalyse verricht naar de volgende zoekvraag:

Wat is bij volwassen patiënten met een laaggradig glioom het effect van chemotherapie/radiotherapie/chemo- en radiotherapie op progressievrije overleving, algehele overleving, kwaliteit van leven en/of cognitie?

Relevante uitkomstmaten

De werkgroep achtte progressievrije overleving, algehele overleving, kwaliteit van leven en cognitie voor de besluitvorming cruciale uitkomstmaten.

Zoeken en selecteren (Methode)

In de databases Medline (via OVID) en Embase (via Embase.com) is op 29 maart 2018 met relevante zoektermen gezocht naar studies die bovengenoemde uitgangsvraag beantwoorden. De zoekverantwoording is weergegeven onder het tabblad Verantwoording. De literatuurzoekactie leverde 514 artikelen op. Studies werden geselecteerd op grond van de volgende selectiecriteria: systematische reviews of meta-analyses, gerandomiseerde gecontroleerde studies of klinische studies, gepubliceerd na 1990 die voldeden aan de

vooraf opgestelde PICO. Op basis van titel en abstract werden in eerste instantie 66 artikelen voorgeselecteerd. Na raadpleging van de volledige tekst, werden vervolgens 53 artikelen geëxcludeerd (zie exclusietabel onder het tabblad Verantwoording) en 13 artikelen definitief geselecteerd.

Verantwoording

Recidief laaggradig glioom

Uitgangsvraag

Wat is de rol van chemotherapie bij een patiënt met een recidief bij een laaggradig glioom?

Aanbeveling

De voorkeur gaat uit naar behandeling in studieverband (TAVAREC NCT01164189 voor patiënten zonder co-deletie van 1p en 19q). Indien geen studie beschikbaar, wordt geadviseerd behandeling met 12 kuren temozolamide te overwegen; voor tumoren met een 1p-19q co-deletie is PCV een optie.

Verdere lijnsbehandeling, bijvoorbeeld PCV of lomustine monotherapie na temozolamide of temozolamide na PCV kan in geselecteerde patiënten overwogen worden.

Overwegingen

Data over welk schema je moet kiezen ontbreken omdat er geen vergelijkende studies zijn in deze setting, maar het ligt voor de hand om bij tumoren met een co-deletie van 1p-19q te kiezen voor PCV, en de patiënten met een tumor zonder 1p/19q co-deletie te behandelen met temozolamide.

Onderbouwing

Achtergrond

Deze module beschrijft de rol van chemotherapie bij een patiënt met een recidief bij een laaggradig glioom, waarbij er sprake is van progressie op beeldvorming na resectie en aanvullende behandeling.

Conclusies

Er zijn aanwijzingen voor respons op temozolamide en PCV bij recidief laaggradige gliomen.

Pace 2003²⁴³, Van den Bent 2003³⁵⁸, Van den Bent 2006³⁵², Van den Bent 2013³⁵¹, Quinn 2003²⁶⁹, Levin 2006²⁰¹

Samenvatting literatuur

Er zijn verschillende studies die de meerwaarde van chemotherapie bij recidief laaggradige (astrocytaire en oligodendrogliale) gliomen aantonen voor zowel PCV [Pace 2003²⁴³, Van den Bent 2003³⁵⁸, 2006³⁵², 2013³⁵¹] als temozolamide [Quinn 2003²⁶⁹, Levin 2006²⁰¹]. De huidige behandelopties geven een kans op respons van ongeveer 50-75% afhankelijk van de morfologie, moleculaire opmaak en voorbehandeling. Voor verdere lijnsbehandeling, bijvoorbeeld PCV of lomustine monotherapie na temozolamide of temozolamide na PCV, is er slechts beperkte data uit ongecontroleerde patiëntseries [Triebels 2004³⁴⁴]

Behandeling Hooggradig glioom

Deze module is onderverdeeld in de volgende submodules en sub-submodules:

- Neurochirurgie
 - Chirurgische behandelingsstrategie hooggradig glioom
 - Minimale mate van resectie hooggradig glioom
 - Waarde en mate van re-resectie glioblastoom
- Radiotherapie
 - Indicatie radiotherapie anaplastisch glioom
 - Indicatie radiotherapie glioblastoom
 - Radiotherapie bij progressie hooggradig glioom/recidief
- Chemotherapie/systeemtherapie
 - Chemotherapie nieuw gediagnosteerd anaplastisch glioom
 - Chemotherapie recidief anaplastisch glioom
 - Chemotherapie nieuw gediagnosteerd glioblastoom
 - Chemotherapie recidief glioblastoom

Verantwoording

Neurochirurgie bij hooggradig glioom

Deze submodule is onderverdeeld in de volgende sub-submodules:

- Chirurgische behandelingsstrategie hooggradig glioom
- Minimale mate van resectie hooggradig glioom
- Waarde en mate van re-resectie glioblastoom

Verantwoording

Laatst beoordeeld : 15-04-2015

Chirurgische behandelingsstrategie hooggradig glioom

Uitgangsvraag

Wat is de beste neurochirurgische behandelingsstrategie bij een patiënt met een vermoedelijk hooggradig glioom op beeldvorming?

Aanbeveling

Er wordt geadviseerd een resectie te verrichten zo maximaal als mogelijk is met behoud van kwaliteit van leven. Zie module Minimale mate van resectie hooggradig glioom.

Voor een patiënt met een vermoedelijk hooggradig glioom dienen de risico's en de voordelen van een zo maximaal mogelijke resectie individueel afgewogen te worden in een multidisciplinaire hersentumorwerkgroep, waaraan tenminste een neurochirurg, neuroloog, neuroradioloog, radiotherapeut, een internist-oncoloog en optioneel een klinisch neuropsycholoog deelnemen. In de multidisciplinaire werkgroep wordt een eerste behandelkeuze met alternatieven geformuleerd.

Onder een zo goed mogelijke neurochirurgische behandeling wordt verstaan een zo maximaal mogelijke resectie van tumorweefsel en necrotisch tumorweefsel waarbij kwaliteit van leven behouden wordt. Verschillende operatietechnieken kunnen naar inzicht en ervaring van het neurochirurgisch team gebruikt worden, zoals neuronavigatie, DTI, 5-ALA, intraoperatieve MRI of mapping met behulp van corticale en subcorticale stimulatie. Er zijn geen argumenten in de literatuur dat het achterwege laten van een of meer van deze technieken de patiënt benadeelt. De effectiviteit van carmustine wafers lijkt te klein in verhouding tot de kostprijs om toe te passen.

Prognostisch ongunstige factoren, zoals hoge leeftijd, lage Karnofsky performance status, multifocaliteit en bilaterale uitbreiding, dienen betrokken te worden in het advies voor de neurochirurgische behandelstrategie. Over het algemeen zal een terughoudender strategie geadviseerd worden bij meer prognostisch ongunstige factoren.

Overwegingen

Hiernavolgend zullen aanbevelingen uit andere richtlijnen en een aantal klinische dilemma's bij de neurochirurgische behandelstrategie worden toegelicht.

De National Comprehensive Cancer Network (Verenigde Staten) beveelt multidisciplinaire indicatiestelling voor een operatie aan in de vorm van, indien mogelijk, een maximale tumorverwijdering met minimale morbiditeit en vaststellen van de mate van resectie door een MRI binnen 72 uur na operatie [NCCN2013]. Indien dit niet haalbaar is, wordt een bipt of een incomplete tumorverwijdering geadviseerd.

Een aantal dilemma's kan zich voordoen rondom behandelbeslissingen bij de verdenking op een hooggradig glioom. Een selectie daarvan zal hier besproken worden aan de hand van de literatuur: de neurochirurgische behandelstrategie voor anaplastisch glioom, voor multifocaal hooggradig glioom, voor bilateraal glioom en voor de oudere patiënt.

In literatuur van de jaren 1980 en 1990 werden patiënten met een anaplastisch glioom (WHO graad III) veelal samengenomen met patiënten met glioblastoom onder de noemer 'hooggradig glioom'. In studies vanaf

ongeveer het jaar 2000, naar het effect van een resectie bij patiënten met een anaplastisch glioom, wordt de mate van resectie als onafhankelijke gunstige prognostische factor gevonden voor overleving en tijd tot progressie [Keles 2006¹⁶⁷], Puduvali 2003²⁶⁵]. Op het moment dat een besluit over de neurochirurgische behandelstrategie genomen moet worden is de histopathologische gradering nog niet bekend. Een deel van de - achteraf - anaplastische gliomen toont geen of beperkte aankleuring met contrast waarbij een T2/FLAIR-geleide resectie werd beoogd. Een ander deel bestaat echter voornamelijk uit contrastaankleuring, waarbij een T1 met contrast gerichte resectie werd uitgevoerd. Er werd geen literatuur gevonden met vergelijkend onderzoek tussen een T1 met contrast gerichte resectie of uitgebreidere T2/FLAIR-resectie bij deze patiënten.

Aan patiënten met meerdere foci van een hooggradig glioom wordt over het algemeen geen resectie geadviseerd. Uit de literatuur is niet duidelijk of een resectie minder effectief is bij multifocaliteit dan bij unifocaliteit. Aan de ene kant is multifocaal glioblastoom geassocieerd met een kortere overleving in case-control onderzoek van 47 patiënten, gematcht voor leeftijd, conditie en mate van resectie: 6 maanden (95%CI 4-10 maanden) bij multifocale lokalisatie, vergeleken met 11 maanden (95%CI 10-19 maanden) in geval van unifocale lokalisatie ($p = 0.02$) [Patil 2012²⁵⁰]. Aan de andere kant wordt in een ander case-control onderzoek van 20 patiënten met een multifocaal glioblastoom, gematcht voor leeftijd, conditie, eloquentie en mate van resectie met een groep met een unifocale lokalisatie, een vergelijkbare overleving gevonden: 9,7 maanden vergeleken met 10,5 maanden ($p = 0.34$) [Hassaneen 2011¹²⁸].

Aan patiënten met een bilateraal hooggradig glioom (zogenaamd vlinderglioom of balkglioom) wordt over het algemeen geen resectie geadviseerd. Uit de literatuur is echter niet duidelijk of een resectie bij deze groep minder effectief is dan bij een unilaterale lokalisatie. In een beschrijving van 23 patiënten met een bilateraal glioblastoom tussen 1990 en 2000 ondergingen 12 een biopt en 11 een resectie [Dziurzynski 2012⁸⁷]. De groep na resectie had een mediane overleving van 8,8 maanden (95%CI 3-14.6 maanden). Er bestaat discussie over de neurochirurgische behandeling bij patiënten met een hooggradig glioom op hogere leeftijd (met als arbitraire grens 70 jaar of ouder). Aan de ene kant is hoge leeftijd een ongunstige prognostische factor voor overleving en voor perioperatieve morbiditeit [Bauchet 2014¹²], aan de andere kant is mate van resectie ook in deze subgroep een onafhankelijke gunstige prognostische factor voor overleving. In een gerandomiseerde klinische studie bij patiënten met een glioblastoom ouder dan 65 jaar werd vastgesteld, dat een resectie resulteerde in een significant langere overleving dan een biopt [Vuorinen 2003³⁷¹].

Tanaka beschreef 105 patiënten met een glioblastoom ouder dan 65 jaar, die werden behandeld tussen 2003 en 2008, waarvan 52 patiënten een biopt ondergingen en 53 een resectie [Tanaka 2013³⁴⁰]. In multivariate analyse was een resectie geassocieerd met een langere overleving (RR 0.54, 95%CI 0.31-0.94, $p = 0.04$) na correctie voor leeftijd, unifocaliteit en adjuvante therapie. Adjuvante therapie lijkt hiervan de belangrijkste factor. Patiënten die adjuvante therapie ondergingen na een resectie leefden langer (11,5 maanden) dan die na een biopt (6,5 maanden). Postoperatieve complicaties werden beschreven bij 26 (25%) patiënten waarvan 16 na biopt. Postoperatieve mortaliteit ontstond bij 4 (4%) patiënten, allen na biopt.

Scott beschreef 206 patiënten met een glioblastoom, ouder dan 70 jaar, behandeld tussen 1979 en 2007, waarvan 113 een biopt ondergingen en 93 een resectie, waarvan 23 een radiologisch complete resectie betrof [Scott 2011³⁰⁴]. In multivariate analyse hadden patiënten na een biopt een kortere overleving dan na een resectie (HR: 3.09, 95%CI 2.09-4.56, $p <0.001$) na correctie voor conditie, bestraling en chemotherapie. Na een biopt werd een mediane overleving van 2,8 maanden geobserveerd en na een resectie van 7,3 maanden ($p <0.001$).

Ewelt beschreef 103 patiënten met een glioblastoom, ouder dan 65 jaar, behandeld tussen 2002 en 2007 [Ewelt 2011⁹³]. De mediane overleving was 2,2 maanden na biopt (95%CI 1,6-2,7 maanden, 43 patiënten), 7,0 maanden na partiële resectie (95%CI 6,3-7,7 maanden, 37 patiënten) en 13,9 maanden na radiologisch complete resectie (95%CI 11,8-15,9 maanden, 23 patiënten) ($p < 0.05$). In multivariate analyse, was een uitgebreidere resectie geassocieerd met een langere overleving (HR 1.987, $p < 0.05$) na correctie voor leeftijd en conditie.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat een resectie voor een hooggradig glioom de levensduur verlengt.
 Hart 2011¹²⁴, Tsitlakidis 2010³⁴⁶, Stummer 2008³²⁸, Lacroix 2001¹⁹⁰, Chaichana 2014⁴⁸, McGirt 2009²¹⁵, Graus 2013, Bauchet 2010, Filippini 2008⁹⁵

Er zijn aanwijzingen dat na een resectie voor een hooggradig glioom de kwaliteit van leven en cognitie niet verslechtert. Bij ongeveer de helft van de patiënten verbetert de conditie. Bij 5 tot 10% van de patiënten leidt de resectie tot complicaties of verminderde conditieën bij minder dan 2% van de patiënten tot postoperatieve mortaliteit.

Daigle 2013⁶⁷, Brown 2005³⁵, Yoshii 2008⁴⁰³, Talacchi 2011³³⁹, Satoer 2014²⁹⁸, Chang 2003⁵², De Witt Hamer 2012⁷⁶, McGirt 2009²¹⁵, Chaichana 2014⁴⁸

Hogere leeftijd, lagere Karnofsky performance status, multifocaliteit en bilaterale uitbreiding zijn geassocieerd met een kortere levensverwachting.

Patil 2012²⁵⁰, Hassaneen 2011¹²⁸, Dziurzynski 2012⁸⁷, Bauchet 2014¹³, Vuorinen 2003³⁷¹, Tanaka 2013³⁴⁰, Scott 2011³⁰⁴

Samenvatting literatuur

De literatuur voor de neurochirurgische behandeling van een vermoedelijk hooggradig glioom wordt achtereenvolgens beschreven aan de hand van een Cochrane review, een systematische review en een meta-analyse en publicaties over effectiviteit van een resectie in termen van overleving, progressievrije overleving, verbetering van verschijnselen en kwaliteit van leven. Daarna wordt het risico van een resectie beschreven. Tot slot de gerandomiseerde klinische studies die over operatietechnieken zijn gepubliceerd.

In een Cochrane review werd één klinische studie geïdentificeerd, waarin tussen biopsie en resectie werd gerandomiseerd bij patiënten ouder dan 65 jaar in Finland tussen 1993 en 1996 [Hart 2011¹²⁴]. De mediane overleving was korter voor de 16 patiënten na biopsie (85 dagen, 95%CI 55-157) dan voor de 14 patiënten na resectie (171 dagen, 95%CI 146-278; $p = 0.0346$). De hazard ratio, gecorrigeerd voor tumorgrading, was 2.621 (95%CI 1.035-6.641; $p = 0.0422$) en, gecorrigeerd voor radiotherapie, 2.729 (95%CI 1.035 7.195; $p = 0.0423$). Hoewel statistisch significante verschillen werden gevonden in overleving is deze studie underpowered en zijn er methodologische beperkingen.

In een meta-analyse naar het verschil tussen een biopt en resectie in termen van overleving, progressievrije overleving en kwaliteit van leven, identificeerde Tsitlakidis dezelfde gerandomiseerde studie en vier retrospectieve studies waarvan de gegevens van 1111 patiënten gepoold werden [Tsitlakidis 2010³⁴⁶]. Een resectie was geassocieerd met een langere overleving dan een biopt (hazard ratio 0.61, 95%CI 0.52-0.71, p

<0.0001). Statistische analyse was niet mogelijk voor progressievrije overleving en kwaliteit van leven, vanwege het ontbreken van voldoende gegevens.

In vier studies is de relatie tussen de mate van resectie en overleving onderzocht in tertiaire verwijsscentra voor hersentumoren, rekening houdend met bekende prognostische factoren als potentiële confounders. Stummer verrichtte een posthoc analyse van prospectief verzamelde gegevens van 243 patiënten met een glioblastoom in het kader van een gerandomiseerde multicenter studie in Duitsland naar conventionele wit licht microscopie versus 5-ALA fluorescentie microscopie [Stummer 2008³²⁸]. De 122 patiënten waarbij na resectie geen tumorrest aantoonbaar was op de MRI hadden een significant langere overleving (16,9 maanden) dan de 121 patiënten met een tumorrest (11,8 maanden) ($p <0.0001$). De hazard ratio voor overleving na een complete versus incomplete resectie was 1.752 (95%: 1.258-2.438; $p = 0.0004$), na correctie voor leeftijd, conditie, preoperatief tumorvolume, eloquentie, midline verplaatsing, oedeem en ependymale infiltratie.

Lacroix beschreef 416 patiënten met een glioblastoom die geopereerd werden tussen 1993 en 1999 [Lacroix 2001¹⁹⁰]. Een uitgebreidere mate van resectie (>98%) was geassocieerd met een langere overleving (mediane overleving 13 maanden, 95%CI 11,4-14,6 maanden), vergeleken met beperktere resecties (8,8 maanden, 95%CI 7,4-10,2 maanden; $p <0.0001$). In multivariate analyse was de hazard ratio 1.4 (95%CI 1.1-1.9) na correctie voor leeftijd, conditie en radiologische necrose. Een langere overleving werd gevonden vanaf 89% tumorresectie (rate ratio 1.3, 95%CI 1.1-1.6, $p = 0.04$).

Sanai beschreef 500 patiënten met een glioblastoom, die geopereerd werden tussen 1997 en 2009 [Sanai 2011²⁹²]. In multivariate analyse was de hazard ratio per procent resectie 0.99 (95%CI 0.98-0.99, $p=0.004$) na correctie voor leeftijd, conditie en resttumor volume. Een langere overleving werd gevonden vanaf 78% tumorresectie.

Chaichana beschreef 259 patiënten met een glioblastoom, die geopereerd werden tussen 2007 en 2011 [Chaichana 2014⁴⁸]. In multivariate analyse was de hazard ratio per procent resectie 0.992 (95%CI 0.987-0.997, $p = 0.003$) na correctie voor leeftijd, chemotherapie wafer, temozolomide, bestraling en preoperatief tumorvolume.

McGirth beschreef 949 patiënten met een WHO-graad III of IV astrocytoom die geopereerd werden tussen 1996 en 2006 [McGirth 2009²¹⁵]. In multivariate analyse was een uitgebreidere resectie geassocieerd met langere overleving (radiologisch complete resectie vergeleken met een incomplete resectie HR: 0.449, $p = 0.001$; radiologisch bijna-complete resectie vergeleken met een incomplete resectie HR 0.614, $p = 0.002$) na correctie voor leeftijd, conditie, chemotherapie wafer, temozolomide en vervolgbehandeling.

In drie studies is de relatie tussen mate van resectie en overleving onderzocht in behandelpatronen van ziekenhuizen zonder specifieke verwijfsfunctie voor gliomen uitgevoerd in verschillende landen.

Vanuit Spanje werden door Graus 834 patiënten met een operatie voor glioblastoom tussen 2008 en 2010 in 19 ziekenhuizen beschreven [Graus 2013]. In multivariate analyse was de overleving van patiënt na een resectie langer dan na een biopt (HR: 0.50; 95%CI, 0.41-0.60; $p<0.001$) na correctie voor leeftijd, conditie, radiotherapie en chemotherapie.

Vanuit Frankrijk werden door Bauchet 952 patiënten met een operatie voor glioblastoom tussen 2004 en 2006 in 43 ziekenhuizen beschreven [Bauchet 2010]. In multivariate analyse was de overleving korter voor patiënten na een biopt dan na een resectie (HR: 1.606, 95%CI 1.255-2.056, $p=0.0002$) na correctie voor leeftijd en tumorlokalisatie.

Vanuit Italië werden door Filippini 676 patiënten met een operatie voor glioblastoom tussen 1997 en 2003 beschreven [Filippini 2008⁹⁵]. In multivariate analyse was de overleving langer voor patiënten na resectie dan

na biopt (HR 0.55, 95%CI 0.42 - 0.72, p<0.001) na correctie voor leeftijd, conditie, tumoruitbreiding, chemotherapie en radiotherapie.

Een aantal studies beschreef het effect van een resectie op de kwaliteit van leven. In een studie met 35 patiënten met een glioblastoom, geopereerd in 2010 en 2011, werd beschreven dat een uitgebreidere resectie gepaard ging met een verbetering in functioneel welbevinden ($r=0.616$, $p=0.005$), een verbetering in neurocognitief functioneren ($r=0.51$, $p=0.026$) en een verbetering in globale kwaliteit van leven ($r=0.68$, $p=0.001$) drie maanden na operatie ten opzichte van voor operatie [Daigle 2013[157]]. In een andere studie met 220 patiënten met een WHO-graad III of IV glioom geopereerd tussen 1999 en 2002 en verzameld in drie klinische studies werd beschreven dat in multivariate analyse patiënten na een radiologisch complete resectie minder risico op een slechte kwaliteit van leven hadden dan patiënten na een biopt (odds ratio: 0.14, 95%CI 0.04-0.57, $p= 0.006$) [Brown 2005³⁵].

Andere studies beschreven de relatie tussen operatie voor hersentumoren, waarvan een deel hooggradig glioom betrof, en cognitie. Yoshii beschreef 31 patiënten, waarvan 23 met een hooggradig glioom, die voor en een maand na operatie neuropsychologisch onderzoek ondergingen [Yoshii 2008⁴⁰³]. De cognitie verbeterde voor patiënten die een operatie ondergingen in de rechter hersenhelft, maar niet in de linker hersenhelft. Talacchi beschreef 29 patiënten waarvan 17 met een hooggradig glioom, die voor en een week na operatie neuropsychologisch onderzoek ondergingen [Talacchi 2011³³⁹]. Tenminste één cognitief domein verbeterde bij 6 (21%) patiënten; tenminste één cognitief domein verslechterde bij 7 (24%) patiënten. Satoer beschreef 45 patiënten waarvan 17 met een hooggradig glioom die voor en drie maanden en een jaar na operatie neuropsychologisch onderzoek ondergingen [Satoer 2014²⁹⁸]. Drie maanden na operatie waren er geen veranderingen in aandacht en executieve vaardigheden, een verbetering in geheugen ($p=0.034$) en een kleine maar significante verslechtering in taalfunctie ($p=0.030$). Tussen drie maanden en een jaar na operatie verbeterde de taalfunctie ($p=0.026$).

Het risico op permanente neurologische en neuropsychologische functiestoornissen na een resectie is 6,2% (3.2-11.5%) in de subgroep van patiënten met een hooggradig glioom in een meta-analyse van 2104 patiënten in 18 studies [De Witt Hamer 2012⁷⁶]. Het risico op postoperatieve mortaliteit is 0,26% (0.01-0.50%).

Stummer beschreef bij 34 (14%) van 235 patiënten met een glioblastoom een functionele achteruitgang zes weken na operatie en bij 95 (40%) een functionele vooruitgang in termen van NIH stroke score (National Institutes of Health) [Stummer 2006³²⁷]. Postoperatieve mortaliteit deed zich voor bij 8 (3%) patiënten.

Chaichana beschreef bij 19 (7%) van 259 patiënten met een glioblastoom een permanente neurologische functiestoornis [Chaichana 2014⁴⁷].

McGirth beschreef bij 63 (7%) van 949 patiënten met een glioblastoom een nieuwe motorische functiestoornis, bij 48 (5%) een nieuwe taalstoornis, bij 22 (2%) een infectieuze complicatie, bij 11 (1%) een postoperatief hematoom, en bij 23 (2%) een longembolie [McGirth 2009²¹⁵].

Chang beschreef bij 8,1% van 408 patiënten met een hooggradig glioom na een operatie een functionele achteruitgang, en bij 53% een functionele verbetering [Chang 2003⁵²]. Een regionale complicatie, zoals een wondinfectie of liquorlekage, ontstond bij 10%; een systemische complicatie, zoals een diepe veneuze trombose of pneumonie, bij 9,2%. Postoperatieve mortaliteit deed zich voor bij 6 (1,5%) patiënten.

Verschillende operatietechnieken zijn geïntroduceerd en geëvalueerd in gerandomiseerde klinische studies: chemotherapie wafer implantatie en beeldgeleide operatie met intraoperatieve MRI, 5-ALA fluorescentie en functionele MRI en diffusion tensor imaging. Deze worden hier achtereenvolgens besproken.

In een Cochrane review [Hart 2011¹²⁴] naar de effectiviteit van chemotherapie geïmpregneerde wafers in de

resectieholte na operatie voor nieuw gediagnosticeerd hooggradig glioom, identificeerden de auteurs twee gerandomiseerde studies met in totaal 272 patiënten, waarin radiotherapie alleen vergeleken werd met radiotherapie plus carmustine wafers [Valtonen 1997³⁴⁸], Westphal 2003³⁸⁴]. Na wafer implantatie werd een langere overleving waargenomen (HR: 0.65, 95%CI 0.48-0.86, p=0.003), zonder verschil in complicaties. De mediane overleving was 13,9 maanden voor de carmustine wafer groep vergeleken met 11,6 maanden voor de placebo groep, met een jaar overleving van 59,2% en 49,6%. Hoewel statistisch significant werd dit verschil geïnterpreteerd als minimaal klinisch relevant. Carmustine wafers worden in Nederland niet vergoed door zorgverzekeraars.

In een Cochrane review [Barone 2014⁹] naar verschillende beeldgeleide operatietechnieken voor optimaliseren van de mate van resectie werden vier gerandomiseerde studies geïdentificeerd: een voor intraoperatieve MRI [Senft 2011³⁰⁶], 5-ALA fluorescentie geleide resectie [Stummer 2006³²⁷], neuronavigatie [Willems 2006³⁸⁹] en DTI-neuronavigatie [Wu 2007³⁹²]. De mate van resectie werd uitgebreider na intraoperatieve MRI (risk ratio voor incomplete resectie: 0.13, 95%CI 0.02-0.96, lage kwaliteit bewijs), na 5-ALA (RR 0.55, 95%CI 0.42-0.71) en DTI-neuronavigatie (RR 0.35, 95%CI 0.20-0.63, erg lage kwaliteit van bewijs). De rapportage van complicaties was onvoldoende voor analyse, terwijl vroege neurologische functiestoornis vaker voorkwamen na 5-ALA resectie. Een overlevingsvoordeel kon niet worden vastgesteld voor 5-ALA (HR: 0.82, 95%CI 0.62-1.07) of DTI-neuronavigatie (HR 0.57, 95%CI 0.32-1.00) voor patiënten met een hooggradig glioom. Progressie-vrije overleving werd niet gerapporteerd.

Senft verrichtte een prospectief gerandomiseerde studie (NCT01394692) naar het effect van intraoperatieve MRI op radiologisch complete resectie bij contrast-aankleurend glioom [Senft 2011³⁰⁶]. Het primaire eindpunt was de mate van tumorresectie op postoperatieve MRI. Secundaire eindpunten waren het resttumor volume op postoperatieve MRI en progressievrije overleving na zes maanden. Er werden 58 patiënten geïncludeerd, waarvan 8 geëxcludeerd werden na randomisatie vanwege de diagnose metastase en 1 op eigen verzoek. Na randomisatie werden 24 patiënten geopereerd met intraoperatieve MRI en 25 zonder. In de intraoperatieve MRI-groep werd een radiologisch complete resectie bij 24 patiënten (96%) vastgesteld en in de controlegroep bij 17 patiënten (68%) (p=0.023). In de intraoperatieve MRI-groep werd minder resttumor geobserveerd dan in de controlegroep (een mediaan resttumorvolume van 0 versus 0.03 mL, p=0.0015). Na zes maanden bestond progressie bij 8 patiënten (33%) in de intraoperatieve MRI-groep en bij 16 patiënten (64%) in de controlegroep (p=0.046).

Wu verrichtte een prospectief gerandomiseerde studie naar het effect van DTI-gebaseerde neuronavigatie tijdens operatie voor gliomen nabij de pyramidebaan op motorische functiestoornissen, de mate van resectie en overleving [Wu 2007³⁹²]. Eindpunten werden niet gedefinieerd. Na randomisatie van 238 patiënten werden er 118 geopereerd met DTI-geleide neuronavigatie en 120 zonder. Een radiologisch complete resectie werd vastgesteld bij 72% in de DTI-geleide neuronavigatie groep en bij 52% in de controlegroep (p=0.002). Na operatie bestond een motorische functiestoornis bij 18 patiënten (15,3%) in de DTI-geleide neuronavigatie groep en bij 39 patiënten (32,8%) in de controlegroep (p<0.001). De gemiddelde KPS bij zes maanden was 86 in DTI-geleide neuronavigatie groep en 74 in de controlegroep (p<0.001). Survivalanalyse werd alleen in de subgroep van 81 patiënten met hooggradig glioom verricht. De mediane overleving in de DTI-geleide neuronavigatie groep met hooggradig glioom was 21,2 maanden en in de controle groep 14,0 maanden (p=0.048).

Stummer verrichtte een prospectief gerandomiseerde studie (NCT00241670) naar het gebruik van porphyrin fluorescentie voor maligne glioom na toedienen van 5-aminolevulinezuur om de mate van resectie op postoperatieve MRI te verbeteren en om de effecten van resectie op progressievrije overleving,

neurologische morbiditeit en vervolgbehandeling te analyseren [Stummer 2006³²⁷]. De primaire eindpunten waren het percentage patiënten zonder aankleurende resttumor op MRI en de progressievrije overleving na zes maanden. Secundaire eindpunten waren het resttumorvolume op MRI, overleving, neurologisch functiestoornissen en toxiciteit. Na interimanalyse bij 270 van 350 benodigde patiënten werd de studie vroegtijdig beëindigd. Na randomisatie werden 139 patiënten geopereerd met 5-ALA fluorescentie licht door de microscoop en 131 met conventioneel witlicht. Contrast-aankleurende tumoren werden in de 5-ALA groep bij 90 (65%) patiënten totaal verwijderd ten opzichte van bij 47 (36%) in de controle groep ($p<0.0001$). In de 5-ALA groep was 41,0% van patiënten progressievrij bij zes maanden vergeleken met 19,9% in de controle groep ($p=0.0003$). De groepen verschilden niet in overleving of postoperatieve complicaties.

Willems verrichtte een prospectief gerandomiseerde studie naar het effect van neuronavigatie op de mate van tumorverwijdering bij contrast-aankleurende hersentumoren [Willems 2006³⁸⁹]. Eindpunten werden niet geformuleerd. Er werden 46 patiënten geïncludeerd (39 hooggradig gliomen, 6 metastasen en 1 later geëxcludeerd meningeoom), waarvan na randomisatie 23 een resectie met neuronavigatie ondergingen en 22 zonder. De mate van tumorverwijdering en de resttumor verschilden niet. De mediane overleving was 5,6 maanden in de groep van resectie met neuronavigatie en 9 maanden in de controle groep ($p=0.037$).

Verantwoording

Minimale mate van resectie hooggradig glioom

Uitgangsvraag

Wat is de minimale mate van resectie die zinvol is bij een patiënt met een hooggradig glioom?

Aanbeveling

Er is geen minimale mate van resectie aan te geven die zinvol is bij de indicatiestelling voor een operatie bij een patiënt met een vermoedelijk hooggradig glioom. Er zijn echter aanwijzingen dat bij een glioblastoom een langere overleving wordt behaald bij een uitgebreidere resectie.

Zie voor de beste neurochirurgische behandelingsstrategie bij een patiënt met een vermoedelijk hooggradig glioom, de module [Chirurgische behandelingsstrategie hooggradig glioom](#).

Het is onduidelijk of de te behalen mate van resectie preoperatief betrouwbaar is in te schatten. In het geval een resectie wordt uitgevoerd, is het meten van de mate van resttumor en de mate van tumorverwijdering met behulp van pre- en postoperatieve MRI aan te bevelen ter verslaglegging (zie module [Beeldvormende diagnostiek](#)).

Overwegingen

Het is maar zeer de vraag of een eenduidige afkapwaarde bestaat waarboven een resectie zinvol is en waar beneden een resectie zinloos is. Deze argumenten zijn verwoord door Solheim [2014³²³]. Ten eerste is een continuüm tussen verlengde overleving door verminderde tumorlast waarschijnlijker dan een exacte afkapwaarde op basis van 'biologica'. Ten tweede moeten klinische relevantie en statistische significantie duidelijk onderscheiden worden: studies met grotere patiëntaantallen zullen kleinere verschillen in overleving als statistisch significant kunnen aantonen, terwijl het natuurlijk gaat om de waarde van de mate van levensverlenging. Ten derde is het onduidelijk of pre-operatief een goede inschatting te geven is van de te verwachten mate van resectie.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat een grotere mate van resectie en minder resttumor na operatie voor een glioblastoom gepaard gaat met een langere overleving.

Chaichana 2014⁴⁸, Sanai 2011²⁹², Lacroix 2001¹⁹⁰, Stummer 2008³²⁸

Er zijn aanwijzingen dat bij een glioblastoom een langere overleving wordt behaald bij minimale resectie van respectievelijk 70% -100%; of als alternatieve mate van resectie uit een maximaal restvolume van nul mL of 5 mL.

Chaichana 2014⁴⁸, Sanai 2011²⁹², Lacroix 2001¹⁹⁰, Stummer 2008³²⁸

Samenvatting literatuur

In de literatuur werden vier publicaties gevonden die deze uitgangsvraag als onderzoeksraag direct

proberen te beantwoorden voor glioblastoom.

Lacroix beschreef 416 patiënten, geopereerd voor glioblastoom tussen 1993 en 1999, waarvan 183 patiënten eerdere tumorbehandeling in een ander centrum ondergingen [Lacroix 2001¹⁹⁰]. De mate van resectie werd op basis van MRI-volumetrie gemeten. In multivariate survivalanalyse werd een afkapwaarde van 98% tumorresectie onderzocht, met correctie voor leeftijd, conditie en radiologische parameters (necrose en aankleuring). Een tumorresectie van 98% of meer was significant geassocieerd (adjusted rate ratio 1.6, 95%CI 1.3-2, p < 0.0001) met een langere overleving: 13 maanden (95%CI 11,4-14,6 maanden) vergeleken met 8,8 maanden (95%CI 7,4-10,2 maanden, p < 0.0001) voor patiënten met minder dan 98% tumorresectie. In univariate analyse werden verschillende afkapwaarden voor mate van resectie geëxploereerd. Tot een minimale afkapwaarde van 89% werd in deze groep een associatie met overleving gevonden.

Stummer beschreef 243 patiënten, geopereerd voor glioblastoom tussen 1999 en 2004, in het kader van een multicenter klinische studie naar een operatietechniek (operatiemicroscopie met 5-ALA fluorescentie) [Stummer 2008³²⁸]. De mate van resttumor werd op basis van MRI-volumetrie gemeten. In een multivariate survivalanalyse werd afwezigheid van aankleurende resttumor onderzocht, met correctie voor leeftijd, conditie, preoperatief tumorvolume, eloquentie, midlijn shift, mate van oedeem en ependymale tumorinfiltratie. Afwezigheid van resttumor was significant geassocieerd (adjusted hazard ratio 1.75, 95%CI 1.26-2.44, p < 0.001) met een langere overleving: 16,9 maanden vergeleken met 11,8 maanden voor patiënten met resttumor. In kaplan meier survivalanalyse naar de afkapwaarde voor de mate van resttumor bleken alle categorieën van resttumor (minder dan 0.7 mL, 0.7-1.5 mL, 1.5-4.1 mL, en meer dan 4.1 mL) significant te verschillen in overleving (p = 0.0006) van de patiënten met afwezigheid van resttumor.

Sanai beschreef 500 patiënten, geopereerd voor glioblastoom tussen 1997 en 2009. De mate van resttumor werd op basis van MRI-volumetrie gemeten [Sanai 2011²⁹²]. In een multivariate survivalanalyse werden zowel het volume resttumor als de mate van tumorresectie onderzocht, met correctie voor leeftijd en conditie. Een uitgebreidere resectie (adjusted hazard ratio per procent tumorverwijdering 0.99, CI95% 0.98-0.99, p = 0.004) en minder resttumor (adjusted hazard ratio per mL 1.07, 95%CI 1.04-1.11, p < 0.0001) waren significant geassocieerd met langere overleving. In kaplan meier survivalanalyse werd een langere overleving waargenomen tot een minimale afkapwaarde van 78%.

Chaichana beschreef 259 patiënten, geopereerd voor glioblastoom tussen 2007 en 2011 [Chaichana 2014⁴⁸]. De mate van resttumor werd op basis van MRI-volumetrie gemeten. In een multivariate survivalanalyse werd zowel de mate van tumorresectie als het volume resttumor onderzocht, met correctie voor leeftijd, conditie, carmustinewafer implantatie en chemoradiatie. Een uitgebreidere resectie (adjusted hazard ratio per vijf procent: 0.948, 95%CI 0.918-0.978, p=0.0005) was significant geassocieerd met een langere overleving. De minimale afkapwaarde voor de mate van tumorresectie die nog geassocieerd was met langere overleving is 70% (adjusted hazard ratio: 0.631, 95%CI 0.462-0.875, p=0.0006). De mediane overleving van patiënten met meer dan 70% tumorverwijdering was 14,4 maanden, vergeleken met 10,5 maanden voor patiënten met minder tumorverwijdering (p=0.0003). Een kleiner resttumorvolume (adjusted hazard ratio per 5 mL resttumor: 1.147, 95%CI 1.053-1.261, p=0.001) was eveneens significant geassocieerd met langere

overleving. De maximale afkapwaarde voor volume resttumor was 5 mL (adjusted hazard ratio: 0.725, 95%CI 0.534-0.991, p=0.01). De mediane overleving van patiënten met minder dan 5 mL resttumor was 14,4 maanden, vergeleken met 10,5 maanden voor patiënten met meer resttumor (p = 0.0003).

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Waarde en mate van re-resectie glioblastoom

Uitgangsvraag

- Wat is de waarde van een re-resectie bij progressie van een glioblastoom?
- Hoe groot moet de resectie zijn bij een patiënt met progressie van een glioblastoom?

Aanbeveling

Patiënten met een recidief glioblastoom dienen in een multidisciplinair neuro-oncologisch overleg te worden besproken. In de recidiefsetting dienen palliatieve behandelingen zoals chirurgie, radiotherapie en chemotherapie telkens in overweging genomen te worden.

Er wordt geadviseerd een re-resectie bij recidief glioblastoom te overwegen bij een patiënt met gunstige prognostische factoren (lagere leeftijd, betere conditie, localisatie tumor, lagere verwachte morbiditeit).

Voor de indicatiestelling van een re-resectie kan de NIH-schaal (National Institutes of Health) gebruikt worden, waarbij meerdere prognostisch ongunstige factoren (tumor eloquent of nabij arteria cerebri media gelegen, KPS <=80, tumorvolume >= 50 mL) geassocieerd zijn met een kortere levensverwachting en dus een terughoudender beleid voor re-resectie.

Overwegingen

Verschillende oorzaken kunnen bijdragen aan bias in de genoemde publicaties. Ziekteprogressie is niet eenduidig gedefinieerd waardoor patiënten met pseudoprogressie kunnen zijn geïncludeerd. Selectie van patiënten speelt waarschijnlijk een rol, waardoor patiënten met een gunstiger prognose oververtegenwoordigd zijn in de groep die een re-resectie onderging en dus de prognose en niet de re-resectie oorzaak is van de langere overleving.

De morbiditeit en mortaliteit varieert tussen de studies. Er worden percentages gemeld voor morbiditeit van 4,1% [Hoover 2013¹⁴¹] tot 45% [De Bonis 2013⁷⁴]. De oorzaak van deze variatie is niet onderzocht. De mortaliteit varieert van 0 % [Pinsker 2001²⁶²] tot 5% [Mandl 2008²⁰⁹].

Het lijkt te overwegen re-resectie te verrichten wanneer post-operatief zinvolle tumorremmende behandeling mogelijk is, al dan niet in studieverband.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat een re-resectie bij progressie van een glioblastoom gepaard gaat met een langere overleving en progressievrije overleving. De mate van selectiebias is onduidelijk en is in de recidief setting groter dan bij de novo tumoren. De resultaten van deze studies moeten daarom met grote voorzichtigheid worden geïnterpreteerd.

Guyotat 2000¹²², Xu 2011³⁹⁵, De Bonis 2013⁷⁴, Bloch 2012²⁰, McGirt 2009²¹⁵

Er zijn aanwijzingen dat een re-resectie gepaard gaat met morbiditeit en mortaliteit, vergelijkbaar met een eerste resectie.

Dutzman 2012⁸⁶

Voor de indicatiestelling van een re-resectie kan de NIH schaal (National Institutes of Health) gebruikt worden, waarbij meerdere prognostisch ongunstige factoren (tumor eloquent of nabij arteria cerebri media gelegen, KPS <=80, tumorvolume >= 50 mL) geassocieerd zijn met een kortere levensverwachting en dus een terughoudender beleid voor re-resectie.

Park 2010²⁴⁹

Er is geen literatuur over de minimale mate van resectie bij progressie van een glioblastoom.

Samenvatting literatuur

In de literatuur worden artikelen gevonden die een resectie bij recidief hooggradig glioom hebben onderzocht. Het betreft niet-vergelijkend cohortonderzoek. Vergelijkend gerandomiseerde studies die deze vraag direct beantwoorden, werden niet gevonden. Alleen publicaties waarin specifiek gekeken is naar overleving en/of progressievrije overleving, en/of morbiditeit en/of mortaliteit met betrekking tot resectie bij recidief hooggradig glioom zijn geïncludeerd. Alleen publicaties na 2000 zijn geïncludeerd.

Guyotat vergeleek 2 groepen patiënten met progressief glioblastoom: 18 patiënten kregen een resectie en 36 patiënten kregen geen resectie [Guyotat 2000¹²²]. De groepen werden gematcht voor leeftijd, conditie, mate van resectie bij eerste operatie en het interval tot progressie. Beide groepen kregen de conventionele nabehandeling (chemo-radiatie). De mediane overleving van patiënten na resectie was vijf maanden versus twee maanden zonder resectie. Het verschil was statistisch significant in de univariate analyse. De mediane overleving met een Karnofsky performance status (KPS) score >60, was voor patiënten na resectie vier maanden, vergeleken met één maand voor patiënten zonder resectie.

Pinsker beschreef 38 patiënten met progressief glioblastoom die een resectie ondergingen tussen 1993 en 1998 (17% van 224 patiënten met een glioblastoom) [Pinsker 2001²⁶²]. De mediane overleving was 57 weken. Een KPS van meer dan 90 was geassocieerd met een langere overleving. Functionele achteruitgang deed zich niet voor. Er was geen perioperatieve mortaliteit.

Mandl onderzocht de effecten op overleving en complicaties van resectie bij progressief glioblastoom voor 32 (25%) van 126 glioblastoom patiënten tussen 1999 en 2005 [Mandl 2008²⁰⁹]. De mediane overleving na progressie was 34 weken (95%CI 24,7-43,4) voor 11 patiënten die resectie gevolgd door nabehandeling ondergingen, 13 weken (95%CI 1,3-24,7) voor 9 patiënten die resectie zonder nabehandeling ondergingen en 28 weken (95%CI 12,1-43,9) voor 12 patiënten die alleen chemotherapie of bestraling ondergingen ($p<0.0005$). Chirurgische morbiditeit ontstond bij drie patiënten (15%); één (5%) patiënt overleed na operatie.

Xu beschreef 63 patiënten met progressie van een glioblastoom tussen 2006 en 2008, waarvan 21 patiënten een resectie ondergingen en 42 niet [Xu 2011³⁹³]. De mediane overleving was voor de geopereerde patiënten zeven maanden en voor de niet geopereerde patiënten vier maanden ($p<0.001$). De tijd tot progressie van tumorgroei was voor de geopereerde patiënten vijf maanden en voor de niet geopereerde

patiënten 2,5 maanden ($p<0.001$).

Clarke beschreef een posthocanalyse van gecombineerde data van fase II studies naar chemotherapie bij progressie van een glioblastoom [Clarke 2011⁶⁰]. Oudere studies (1998-2005) bevatten 105 patiënten van 511 die een operatie (biopsie of resectie) ondergingen en nieuwere studies (2005-2008) bevatten 103 patiënten van 247 die een operatie (biopsie of resectie) ondergingen. De overleving of progressievrije overleving van patiënten die een operatie (biopsie of resectie) ondergingen verschilde niet van patiënten die geen operatie ondergingen.

Dutzman onderzocht het risico op ischemie en neurologische uitval bij re-resectie bij recidief groei van het glioblastoom [Dutzman 2012⁸⁶]. Van de 177 beschreven patiënten werden 130 patiënten (73,3%) één maal geopereerd en 47 (26,5%) twee of meerdere malen geopereerd. Bekende prognostica waren evenredig verdeeld over beide groepen. 46 patiënten (26%) hadden ischemie (DWI) op de postoperatieve MRI. Bij 18 patiënten (10,2%) was de ischemie groter dan 4 cm³. Elf van deze patiënten (6,2%) hadden ook neurologische uitval. Er was echter geen verschil in ontstaan van ischemie (27.7 vs. 21.3%, $p=0.77$) en neurologische uitval (10.0 vs. 10.6%, $p=1.0$) tussen de groepen die één maal of meer dan één maal werd geopereerd. Tumorlocatie in de insula, operculum en temporaalkwab was wel geassocieerd met ontstaan van nieuwe ischemische laesies.

Moiyadi onderzocht in een cohort de postoperatieve complicaties bij patiënten met progressie van een glioblastoom [Moiyadi 2012²¹]. Er werden 41 re-operaties in een database van 196 operaties voor gliomen geëvalueerd. Neurologische achteruitgang werd beschreven bij 22,2% van de patiënten. Bij 44% van de patiënten was er sprake van neurologische verbetering na de re-operatie. Bij 14,2% van de patiënten werden regionale en bij 4,8 % werden systemische complicaties gemeld. De morbiditeit was 29,3% en de mortaliteit was 2,4%.

De Bonis onderzocht de effectiviteit van resectie en adjuvante behandeling op overleving bij 76 patiënten met progressie van een glioblastoom behandeld tussen 2002 en 2008 [De Bonis 2013⁷⁴]. Zeventien patiënten ondergingen alleen een resectie, 24 alleen adjuvantetherapie, 16 resectie en adjuvante therapie, en 19 geen behandeling. Dit ging gepaard met een mediane overleving van 6, 8, 14 en 5 maanden ($p=0.01$). Patiënten met een KPS <70 hadden een significant hoger risico om te overlijden (HR 2.8; $p=0.001$). Subgroepanalyse toonde geen significante verschillen in overleving tussen een radiologisch complete of incomplete resectie. Ook was er geen verschil in patiënten die verschillende adjuvante therapieën kregen. Postoperatieve complicaties deden zich voor bij 16 (48%) van de 33 geopereerde patiënten.

Bloch onderzocht de relatie tussen de mate van resectie en de overleving bij 107 patiënten, die een tweede resectie ondergingen bij progressie van een glioblastoom tussen 2005 en 2009 [Bloch 2012²⁰]. De mediane overleving vanaf de eerste diagnose was voor 31 patiënten met een radiologisch complete resectie bij zowel eerste als tweede resectie 20,4 maanden. Voor 21 patiënten met een radiologisch complete resectie bij eerste en een partiële resectie bij tweede operatie was deze 18,4 maanden. Voor 26 patiënten met een partiële resectie bij eerste en een radiologisch complete resectie bij tweede operatie was deze 19 maanden. En voor 29 patiënten met zowel bij eerste als tweede operatie een partiële resectie was deze 15,9 maanden ($p = 0.004$). De mediane overleving vanaf progressie verschilde eveneens: respectievelijk 11.5, 8.5, 16.7 en

7.4 maanden ($p = 0.001$). In multivariate analyse was een uitgebreidere resectie geassocieerd met een langere overleving (HR: 0.62, 95%CI 0.41-0.93, $p = 0.03$) na correctie voor leeftijd, conditie bij eerste resectie, conditie bij tweede resectie en mate van eerste resectie.

Hong beschreef 42 patiënten met progressief glioblastoom die werden geopereerd tussen 2006 en 2010, waarvan 34 patiënten een radiologisch complete re-resectie ondergingen en 10 patiënten met herhaalde re-resecties [Hong 2013¹⁴⁰]. De overleving na radiologisch complete re-resectie was 16 maanden en na incomplete resectie 14 maanden (HR 1.86, 95%CI 0.86-3.92; $p=0.112$).

Park beschreef 34 patiënten met een progressief glioblastoom op basis waarvan een prognostisch model voor overleving na re-resectie werd opgesteld [Park 2010²⁴⁹]. Een kortere overleving na re-resectie was geassocieerd met tumor in eloquente of kritische gebieden, een KPS ≤ 80 , en een tumorvolume ≥ 50 mL. Met deze drie factoren werden een totaalscore samengesteld van 0 tot 3 (voor aan-/afwezigheid van elk van deze factoren). Een score van 0, 1-2 en 3 was respectievelijk geassocieerd met een postoperatieve overleving van 10.8, 4.5 en 1.0 maanden ($p <0.001$). In een validatie cohort van 109 patiënten met een progressief glioblastoom werd deze score geverifieerd, waarbij de prognostische waarde bevestigd werd met 9.2, 6.3 en 1.9 maanden, respectievelijk (HR 3.0, 95%CI 1.54-5.83, $p<0.001$).

McGirt beschreef 949 patiënten met een WHO-graad III of IV astrocytoom die geopereerd werden tussen 1996 en 2006, waarvan 400 een re-resectie ondergingen [McGirt 2009²¹⁵]. Na een radiologisch complete re-resectie was de mediane overleving elf maanden, na een bijna complete re-resectie negen maanden en na een subtotalresectie vijf maanden. In multivariate analyse was een uitgebreidere re-resectie geassocieerd met langere overleving (radiologisch complete resectie vergeleken met een subtotalresectie HR 0.566, $p = 0.002$; radiologisch bijna-complete resectie vergeleken met een subtotalresectie HR 0.630, $p = 0.004$) na correctie voor leeftijd, conditie, motorische uitval, temozolamide en vervolgoperaties.

Radiotherapie bij hooggradig glioom

Deze submodule is onderverdeeld in de volgende sub-submodules:

- Indicatie radiotherapie anaplastisch glioom
- Indicatie radiotherapie glioblastoom
- Radiotherapie bij progressie hooggradig glioom/recidief

Verantwoording

Indicatie radiotherapie anaplastisch glioom

Uitgangsvraag

Wat is de indicatie voor radiotherapie bij een patiënt met een anaplastisch glioom (WHO graad III) en hoe dient dit uitgevoerd te worden?

Aanbeveling

Het meest gangbare fractioneringschema voor het anaplastisch glioom bedraagt 59.4 Gy in 33 fracties van 1.8 Gy gegeven in vijf fracties per week. De werkgroep is van mening dat dit tenminste met 3D conformal radiation therapy (3DCRT-techniek) dient te worden gegeven.

Er wordt geadviseerd, in afwachting van de resultaten van de EORTC-26053-studie (CATNON), patiënten met een anaplastisch glioom zonder gecombineerde 1p/19q-deletie te behandelen met postoperatieve radiotherapie alleen.

Patiënten met een anaplastisch glioom met een 1p/19q-deletie dienen post-operatief behandeld te worden met radiotherapie gevuld door zes kuren PCV, volgens het EORTC-26951-protocol.

De werkgroep is van mening dat op indicatie, bijvoorbeeld bij groot bestralingsvolume en daardoor verhoogd risico op toxiciteit van radiotherapie, overwogen kan worden patienten met een anaplastisch glioom te behandelen met chemotherapie (PCV of temozolamide) in plaats van radiotherapie.

Overwegingen

Naar aanleiding van de resultaten van de NOA-4 studie, waarbij geen verschil tussen RT, PCV of temozolamide werd gevonden in de mediane tijd tot progressieve ziekte bij postoperatieve nabehandeling van anaplastische gliomen zonder 1p/19q-deletie, zou bij een zeer groot doelvolume en een hierbij te verwachten grote kans op toxiciteit van radiotherapie, overwogen kunnen worden te kiezen voor temozolamide als postoperatieve behandeling [Wick 2009³⁸⁶].

Moderne radiotherapie dient tenminste uitgevoerd te worden met 3D conformal radiation therapy. In veel centra worden geavanceerde technieken als intensity modulated radiotherapy, volumetric arc therapy of tomotherapy gebruikt, teneinde het hoge dosis gebied zo optimaal mogelijk te laten aansluiten bij het doelgebied. Er bestaat echter geen bewijs dat geavanceerde planningstechnieken de prognose verbeteren of het risico op complicaties verminderen. Vanwege vroege veranderingen in het operatiegebied en de mogelijkheid van snelle progressie bij het hooggradig glioom is het aan te bevelen de MRI zo kort mogelijk aan te laten sluiten bij het begin van de radiotherapie. In gevallen waarbij er een langer interval tussen de operatie en start radiotherapie bestaat, dient de postoperatieve MRI dan ook herhaald te worden ten behoeve van accurate vaststelling van doelgebieden. Het te bestralen gebied omvat de resectieholte, het (resterende) aankleurende gebied op de T1-contrastsequentie van de (postoperatieve) MRI met 1,5-2 cm marge voor microscopische ziekte, waarbij het hyperintense gebied op de T2/FLAIR-sequenties wordt

geïncludeerd conform de recente en lopende EORTC studies (CATNON, CODEL). Tenslotte worden de natuurlijke barrières in acht genomen. Wanneer er alleen een biopsie is verricht, volstaat de preoperatieve MRI-scan.

Onderbouwing

Conclusies

Het is aannemelijk dat voor het anaplastisch glioom, een bestralingsdosis van 59.4 Gy in 33 fracties van 1.8 Gy gegeven in 5 fracties per week, effectief is. Er zijn geen aanwijzingen dat een hogere bestralingsdosis effectiever is.

Bleehen 1991¹⁸

Toevoeging van PCV aan postoperatieve radiotherapie resulteert in een aanzienlijke verbetering van de overleving bij anaplastische gliomen met een 1p/19q-deletie ten opzichte van postoperatieve radiotherapie alleen.

Cairncross 2013⁴¹, Van den Bent 2013³⁵¹

Er is geen bewijs dat de toevoeging van PCV chemotherapie aan postoperatieve radiotherapie een toegevoegde waarde heeft in de behandeling van het anaplastische glioom zonder een 1p/19q-deletie.
Cairncross 2013⁴¹, Van den Bent 2013³⁵¹

De gecombineerde behandeling met postoperatieve radiotherapie en PCV bleek geen verslechtering van cognitie of kwaliteit van leven te veroorzaken op de lange termijn ten opzichte van radiotherapie alleen.
Van den Bent 2013³⁵¹, Habets 2014¹²³, Wang 2010³⁷⁵

Samenvatting literatuur

Tot de anaplastische gliomen, ook geduid als WHO graad III tumoren, worden de verschillende subtypes anaplastisch astrocytoom, anaplastisch oligodendrogloom en anaplastisch oligoastrocytoom gerekend [Louis 2007²⁰⁴].

Postoperatieve radiotherapie is van oudsher het standaard beleid bij anaplastisch glioom, hoewel de exacte bewijsvoering hiervoor beperkt is. De hierover gerapporteerde studies bevatten een combinatie van patiënten met hooggradige gliomen (HGG), waarbij het aantal geïncludeerde patiënten met een anaplastisch glioom veelal te gering was voor subanalyses. Daarnaast waren de studies verschillend van opzet wat betreft bestralingsdoses, definitie van doelgebieden en het al dan niet gecombineerd toedienen van bestraling en chemotherapie [Walker 1978³⁷³, Kristiansen 1981¹⁸³, Gannett 1994¹⁰⁶, Laperierre 2002¹⁹¹, Mukherjee 2013]²²³.

De meest gangbare bestralingsdosis voor het anaplastisch glioom bedraagt 59.4 Gy in 33 fracties van 1.8 Gy gegeven in 5 fracties per week, waarbij de kans op late neurotoxiciteit wordt verlaagd door het gebruik van een lage dosis per fractie. Voor hooggradig glioom WHO graad III en IV, werd een dosis respons relatie tussen 45 Gy en 60 Gy aangetoond in een oudere MRC studie; er bestaan geen gerandomiseerde data over het nut van een hogere bestralingsdosis [Bleehen 1991¹⁸].

In toenemende mate spelen moleculaire markers een rol in de diagnose en de behandeling van het anaplastisch glioom, zoals bijvoorbeeld de MGMT-promotor methylatie, IDH-mutaties en het gecombineerde verlies van 1p/19q [Roth 2013²⁸³, Gorlia 2013¹¹³], zie ook de module Moleculaire veranderingen diffuse gliomen. Het betrekken van de histologie, moleculaire markers met name het gecombineerde 1p/19q-verlies, en andere individuele patiëntkarakteristieken geeft richting aan het bepalen van postoperatieve therapie bestaande uit radiotherapie, een gecombineerde behandeling of chemotherapie alleen.

Het anaplastische astrocytoom is het meest voorkomende subtype van het anaplastisch glioom, waarbij gecombineerd 1p/19q-verlies vrijwel niet wordt gezien (gemistocytair type 0%, fibrillaire-type 7%) [Ohgaki 2005²³⁵]. De standaardbehandeling van anaplastische astrocytoom bestaat uit postoperatieve radiotherapie zonder chemotherapie. Omdat door velen het anaplastische astrocytoom wordt gezien als een voorloperstadium van het glioblastoom wordt internationaal veelvuldig volgens het EORTC 'Stupp-schema' behandeld met gelijktijdig en adjuvant temozolamide (TMZ), zonder dat hier bewijsvoering voor is. Om de waarde van concomitante en adjuvante chemotherapie vast te stellen bij het anaplastische astrocytoom dienen de resultaten van de lopende CATNON-studie (EORTC-26053) afgewacht te worden. In deze studie worden patiënten met een anaplastische astrocytoom (en het anaplastisch oligodendroglioom en anaplastisch oligoastrocytoom zonder 1p/19q-verlies) gerandomiseerd naar een van de vier armen (radiotherapie alleen, radiotherapie met alleen concomitante TMZ, radiotherapie met alleen adjuvante TMZ, of radiotherapie met concomitante en adjuvante TMZ).

Op het gebied van de anaplastisch oligodendroglioom en anaplastisch oligoastrocytoom-subtypes hebben zich de laatste jaren veel ontwikkelingen voorgedaan. Gecombineerd verlies van 1p/19q komt, in tegenstelling tot bij anaplastische astrocytoom, zeer frequent voor, bijvoorbeeld bij ongeveer 76% van het anaplastisch oligodendroglioom en 24% bij het anaplastisch oligoastrocytoom in de hierna besproken RTOG-studie [Cairncross 2013⁴¹]. De langetermijnresultaten van de EORTC-26951-studie en de RTOG-9402 studie, waarbij werd gerandomiseerd werd tussen radiotherapie alleen of in combinatie met PCV (procarbazine, lomustine, vincristine), lieten beiden een significant voordeel zien voor de gecombineerde behandeling bij patiënten met 1p/19q-verlies (14,7 versus 7,3 jaar in de RTOG-studie - mediane overleving niet bereikt - versus 112 maanden in de EORTC-studie) [Van den Bent 2013³⁵¹, Cairncross 2013⁴¹]. In de groep patiënten zonder 1p/19q-verlies werd geen voordeel van de gecombineerde behandeling gevonden (2,6 versus 2,7 jaar). Hoewel de gecombineerde behandeling met PCV meer vroege (hematologische) toxiciteit veroorzaakt, is hiervan geen negatief effect op de cognitie of kwaliteit van leven aangetoond [Van den Bent 2013³⁵⁴, Habets 2014¹²³, Wang 2010³⁷⁵]. Deze resultaten maken radiotherapie gecombineerd met PCV de huidige standaardbehandeling voor patiënten met anaplastisch oligodendroglioom of anaplastisch oligoastrocytoom met gecombineerd 1p/19q-verlies. Voor patiënten zonder deze gecombineerde deletie is, in afwachting van de resultaten van de CATNON-studie, postoperatieve radiotherapie alleen de standaardbehandeling.

Indicatie radiotherapie glioblastoom

Uitgangsvraag

Wat is de indicatie voor radiotherapie bij een patiënt met een glioblastoom (WHO graad IV) en hoe dient dit uitgevoerd te worden?

Aanbeveling

Bij patiënten met een glioblastoom in goede klinische conditie, jonger dan 61 jaar dient post-operatief een radiotherapiedosis van 30 x 2 Gy gegeven te worden, gecombineerd met concomitant en adjuvant temozolamide. Voor de behandeling van oudere patiënten met een glioblastoom wordt verwezen naar de module Behandeling van ouderen.

Er wordt geadviseerd geen hogere bestralingsdosis toe te dienen. De werkgroep adviseert hypofractionering te overwegen bij patiënten die in een matige conditie zijn.

De werkgroep is van mening dat het doelgebied van de bestraling de resectieholte, het (resterende) aankleurende gebied op de T1-sequentie met contrast van de postoperatieve MRI, met een marge van 1,5-2 cm voor microscopische ziekte, het doelgebied zou moeten zijn. Hierbij wordt rekening gehouden met het hyperintense gebied op de T2- en FLAIR-sequenties en de anatomische barrières.

Overwegingen

De gecombineerde behandeling van hoge dosis radiotherapie en temozolamide toont de meeste winst in overleving in de groep patiënten <50 jaar in een goede postoperatieve conditie. Bij patiënten met een KPS <70 en een leeftijd ≥50 jaar is de winst van de gecombineerde behandeling beperkt.

Als er tijdens het behandelen klachten ontstaan die veroorzaakt worden door (radiotherapie-geïnduceerd) oedeem, kan het starten met (een lage dosis) dexamethason geïndiceerd zijn.

De planning en uitvoering van de bestraling dient tenminste plaats te vinden met behulp van een 3DCRT-techniek. Teneinde het hoge dosis gebied zoveel mogelijk te beperken tot het doelgebied, wordt het gebruik van meer geavanceerde technieken zoals intensity modulated radiotherapy (IMRT), volumetric arc therapy of tomotherapie, aangemoedigd. Er bestaat echter geen bewijs dat geavanceerde planningstechnieken de prognose verbeteren of het risico op toxiciteit verminderen. Vanwege vroege veranderingen in het operatiegebied en de mogelijkheid van snelle progressie bij het GBM is het aan te bevelen de MRI zo kort mogelijk aan te laten sluiten bij het begin van de radiotherapie. In gevallen waarbij er een langer interval tussen de operatie en start radiotherapie bestaat, dient de postoperatieve MRI dan ook herhaald te worden ten behoeve van accurate vaststelling van doelgebieden.

Onderbouwing

Conclusies

Postoperatieve radiotherapie is standaardbeleid na resectie van een glioblastoom, indien de klinische situatie van de patiënt dit toelaat. Een overlevingsvoordeel is aangetoond bij een dosis van 60 Gy ten opzichte van 45

Gy, echter de mediane overleving lijkt niet te verbeteren bij verdere ophoging van de totale bestralingsdosis. Walker 1979³⁷⁴, Bleehen 1981¹⁹, Nelson 1988²²⁶, Nakagaya 1998²²⁴, Chan 2002⁵⁰

Er zijn aanwijzingen dat postoperatieve hypofractionering een gelijkwaardige uitkomst geeft als conventioneel gefractioneerde radiotherapie, maar dit is met name onderzocht bij patiënten met een ongunstige prognose in een niet gerandomiseerde setting en bij oudere patiënten. Slotman 1996³¹⁷, Sayin 2007²⁹⁹, Hingorani 2012¹³⁵

Het is aangetoond dat een hogere lokale bestralingsdosis met behulp van een stereotactische radiochirurgie of brachytherapieboost geen voordeel biedt ten opzichte van standaarddosis bestraling. Souhami 2004³²⁴, Laperriere 1998¹⁹²

Het is aangetoond dat gecombineerd postoperatieve radiotherapie (60 Gy/30 fracties) met gelijktijdig en adjuvant temozolamide een voordeel in overleving biedt ten opzichte van radiotherapie alleen. Stupp 2005³³¹, 2009³³⁰

Samenvatting literatuur

Bij ongeveer 80% van de patiënten die zich presenteren met een hooggradig glioom is sprake van een glioblastoom (WHO graad IV) [Omuro 2013²³⁸]. Zowel tumor- als patiëntgerelateerde factoren, zoals de mate van resectie, de leeftijd en de klinische/neurologische conditie (Karnofsky performance score, KPS), hebben een impact op de prognose en dienen meegenomen te worden bij het afstemmen van de postoperatieve behandeling en het bestralingsschema. Gezien het palliatieve karakter van de behandeling moet overlevingswinst worden afgewogen tegen de morbiditeit van de behandeling en het effect op de kwaliteit van leven. De behandeling van het glioblastoom bij de oudere patiënt wordt afzonderlijk in de module Behandeling van ouderen besproken.

De waarde van postoperatieve radiotherapie bij de behandeling van patiënten met een glioblastoom is in meerdere gerandomiseerde studies aangetoond, waarbij er een winst in mediane overleving wordt gezien van rond de 5 maanden ten opzichte van resectie alleen [Walker 1979³⁷⁴, Kristiansen 1981¹⁸³].

Het bestralingsvolume omvat de resectieholte, het (resterende) aankleurende gebied op de T1- sequentie met contrast van de postoperatieve MRI. Een marge van 1,5-2 cm voor microscopische ziekte (clinical target volume, CTV) wordt aangehouden, waarbij het hyperintense gebied op de T2- en FLAIR-sequenties wordt geïncludeerd. Het CTV kan worden aangepast op basis van anatomische barrières. Er zijn echter geen aanwijzingen dat krappere marges het patroon van recidiveren van het glioblastoom beïnvloedt (80% recidiveert binnen 2 cm van de oorspronkelijke tumor) [McDonald 2011²¹³, Paulsson 2014²⁵²]. Wanneer er alleen een biopsie is verricht volstaat de preoperatieve MRI-scan.

In oudere gerandomiseerde studies is een overlevingsvoordeel aangetoond van een dosis van 60 Gy ten opzichte van een dosis van 45 Gy [Walker 1979³⁷⁴, Bleehen 1981¹⁹]. De mediane overleving werd niet verbeterd bij het verhogen van de dosis van 60 naar 70 Gy (9.3 versus 8.2 maanden) [Nelson 1988²²⁶, Nakagaya 1998²²⁴, Chan 2002⁵⁰]. In een gerandomiseerde studie werd geen voordeel gezien van de toevoeging van stereotactische radiochirurgie (SRS) als boost aan conventionele radiotherapie [Souhami 2004³²⁴]. Evenmin kon een gerandomiseerde studie een verbetering van de overleving door de toevoeging

van brachytherapie aan conventionele radiotherapie aantonen [Laperriere 1998¹⁹²]. Gezien de beperkte levensverwachting van patiënten met een glioblastoom heeft men in verschillende studies gekeken naar het verkorten van de behandelduur met behulp van hypofractionering, vooral bij patiënten met een ongunstige prognose [Slotman 1996³¹⁷, Sayin 2007²⁹⁹]. Een overzichtsartikel over hypofractionering bij het glioblastoom concludeert aan de hand van studies met verschillende bestralingsschema's, uiteenlopend van 30 Gy in 6 fracties tot 54 Gy in 18 fracties, dat hiermee een gelijkwaardige uitkomst wordt gezien als met conventionele fractionering; dit ondanks een lagere totale bestralingsdosis. Er werd geen toename van toxiciteit gezien van hypofractionering [Hingorani 2012¹³⁵]. In de groep patiënten van 60 jaar of ouder met een glioblastoom is behandeling met hypofractionering in een gerandomiseerde setting vergeleken met conventionele fractionering, waarbij een vergelijkbare overleving werd gezien [Roa 2004²⁷⁹]. In de module Behandeling van ouderen wordt verder ingegaan op de Nordic trial die bij patiënten van 60 jaar of ouder met een glioblastoom gerandomiseerd heeft tussen behandeling met een gehypofracioneerd bestralingsschema, conventionele fractionering en TMZ [Hingorani 2012¹³⁵].

De toevoeging van chemotherapie in de vorm van temozolomide (TMZ) aan postoperatieve radiotherapie in een dosis van 60 Gy in fracties van 2 Gy, is sinds de uitkomst van de EORTC- 26981/22981-NCIC CE3-studie de standaardbehandeling na resectie van het glioblastoom [Stupp 2005³³¹]. In een update van de resultaten van de genoemde EORTC-studie werd het significante voordeel van de gecombineerde behandeling bevestigd met een 5-jaars overleving van 10% voor de gecombineerde behandeling versus 2% met radiotherapie alleen. Het overlevingsvoordeel van de gecombineerde behandeling was het grootst in de groep patiënten jonger dan 50 jaar met een KPS van 90-100, waarbij de 2-jaars overleving toenam van 20% naar 43% en de 5-jaars overleving 28% was [Mirimanoff 2006²²⁰, Stupp 2009³³⁰]. Bij patiënten, waarbij zowel de KPS <70 was als de leeftijd ≥50 jaar, en bij patiënten met neurologische uitval, was de winst van de gecombineerde behandeling beperkt: 10 maanden ten opzichte van 9 maanden voor radiotherapie alleen [Mirimanoff 2006²²⁰, Stupp 2009³³⁰]. In enkele kleine prospectieve- en retrospectieve studies is gehypofracioneerde radiotherapie gecombineerd met TMZ bestudeerd, vooral bij oudere patiënten [Hingorani 2012¹³⁵].

Radiotherapie bij progressie hooggradig glioom/recidief

Uitgangsvraag

Wat is de indicatie voor radiotherapie bij een patiënt met een recidief of progressie van een hooggradig glioom in een eerder bestraald gebied en hoe dient deze uitgevoerd te worden?

Aanbeveling

Patiënten met een recidief hooggradig glioom dienen in een multidisciplinair neuro-oncologisch overleg besproken te worden. In de recidiefsetting dienen alle palliatieve behandelingen, waaronder radiotherapie en chirurgie, telkens mede in overweging genomen te worden.

De werkgroep is van mening dat behandeling in studieverband de voorkeur verdient.

De werkgroep is van mening dat een minimaal interval van zes tot twaalf maanden aangehouden dient te worden tussen de initiële bestraling en re-irradiatie.

Bij de afweging of re-irradiatie een reële optie is, speelt de definitie van het doelgebied de belangrijkste rol. De toepassing van kleinere marges dan in de primaire setting wordt geadviseerd.

Om het risico op radiatie-geïnduceerde complicaties zoveel mogelijk te beperken wordt geadviseerd re-irradiatie te plannen met moderne bestralingstechnieken zoals stereotactische radiotherapie, intensity modulated radiotherapy (IMRT) of volumetric modulated arc therapy (VMAT).

De werkgroep is van mening dat er vanuit de literatuur geen optimaal fractioneringsschema vast te stellen is. Voor zowel conventioneel gefractioneerde schema's, hypofractionering of een enkele fractie radiochirurgie zijn series in de literatuur beschreven.

Overwegingen

Er bestaat geen standaardbehandeling voor een recidief hooggradig glioom (HGG), zodat de werkgroep van mening is dat de eerste keuze voor patiënten in goede conditie een behandeling in studieverband is.

Patiënten met een recidief HGG dienen in een neuro-oncologisch multidisciplinair overleg besproken te worden, temeer daar er verschillende behandelopties, zoals reresectie, (tweedelijns)chemotherapie, gerichte medische therapieën, re-irradiatie of combinaties bestaan.

Onderbouwing

Conclusies

Vanwege het ontbreken van gerandomiseerde studies die reresectie, re-irradiatie, (tweedelijns)chemotherapie of gerichte medische therapieën met elkaar hebben vergeleken, bestaat er geen standaardbehandeling voor patiënten met een recidief hooggradig glioom.

Amichetti 2011⁵

Er zijn aanwijzingen dat een minimaal interval van zes tot twaalf maanden moet worden aangehouden tussen de initiële bestraling en re-irradiatie.

Niyazi 2011²³¹

Het is aannemelijk dat de definitie van het doelgebied de belangrijkste afweging is met betrekking tot de mogelijkheid en verwachte toxiciteit van re-irradiatie [Nieder 2011[220]]. In de meeste series wordt het doelgebied bepaald door de contrast-aankleurende gebieden op MRI met geringe marges van 0,5-1 cm. Henke 2009¹³³, Fokas 2009¹⁰¹, Combs 2005⁶⁴, Vordermark 2005³⁶⁹

Er zijn aanwijzingen dat moderne bestralingstechnieken zoals stereotactische radiotherapie, intensity modulated radiotherapy (IMRT) of (volumetric modulated arc therapy) VMAT, het eerder bestraalde hersenweefsel minder belasten, waardoor het risico op radiatie-geïnduceerde complicaties kleiner wordt. Fogh 2010¹⁰⁰

Gezien de diversiteit van de studies is er geen goede aanbeveling voor het optimale fractioneringschema te verkrijgen uit de literatuur.

Hoewel niet gerandomiseerd onderzocht, lijkt de toevoeging van chemotherapie aan re-irradiatie de overleving niet te verbeteren.

Amichetti 2011⁵

Samenvatting literatuur

Hoewel er de laatste jaren vooruitgang is geboekt in de behandeling van geselecteerde patiënten met een hooggradig glioom (HGG) met de combinatiebehandeling bestaande uit chirurgie, radiotherapie en chemotherapie, ontstaat een recidief in ongeveer 90% van de patiënten binnen het eerdere bestralingsgebied [Niyazi 2011²³¹, Amichetti 2011⁵, Weller 2013³⁷⁸]. Het onderscheid tussen radiatie-geïnduceerde veranderingen en tumorprogressie op grond van de beeldvorming kan lastig zijn en wordt besproken in evidence based vraag 1. Bij blijvende twijfel is histologische verificatie noodzakelijk voor het starten van tweedelijnsbehandeling, zeker ook indien re-irradiatie wordt overwogen.

Omdat bij een recidief HGG verschillende palliatieve behandelmogelijkheden vorhanden zijn zoals reresectie, (tweedelijns)chemotherapie, re-irradiatie of combinaties hiervan, dient bespreking in een neuro-oncologisch MDO plaats te vinden. Er bestaan geen gerandomiseerde studies in de recidief HGG setting die de genoemde behandelmogelijkheden vergelijken. In module 2.1 en 2.2 wordt ingegaan op de rol van reresectie en (tweedelijns)chemotherapie en gerichte medische therapieën bij een recidief HGG. De keuze van behandeling wordt vooral bepaald door factoren als klinische conditie, interval tussen initiële behandeling en diagnose van recidief, en de uitgebreidheid en lokatie van het recidief. Door het bovenstaande bestaat er geen standaardbehandeling voor patiënten met een recidief HGG en is de eerste keuze voor patiënten in goede conditie een behandeling in studieverband [Amichetti 2011⁵].

In tegenstelling tot de radiotherapie voor het primair HGG bestaat er geen consensus in de literatuur over het optimale fractioneringsschema of de vaststelling van doelgebieden bij re-irradiatie van HGG. Wel wordt in de meeste studies een minimaal interval van zes tot twaalf maanden aangehouden tussen de eerdere bestraling en re-irradiatie [Niyazi 2011²³¹]. De belangrijkste afweging met betrekking tot de mogelijkheid en verwachte toxiciteit van re-irradiatie betreft niet zozeer de gebruikte bestralingsdosis, maar de definitie van

het doelgebied [Nieder 2011²²⁸]. In de meeste gerapporteerde studies wordt het doelgebied bepaald door de contrast-aankleurende gebieden op MRI met geringe marges van 0,5-1 cm, zonder de witte stof afwijkingen op de T2 sequenties te includeren zoals gebruikelijk in de primaire behandeling [Henke 2009¹³³, Fokas 2009¹⁰¹, Combs 2005⁶⁴, Vordermark 2005³⁶⁹]. Moderne bestralingstechnieken zoals stereotactische radiotherapie, intensity modulated radiotherapy (IMRT) of volumetric modulated arc therapy (VMAT) maken precisiebestraling mogelijk, waardoor de dosis van het eerder bestraalde hersenweefsel en daarmee het risico op radiatie-geïnduceerde complicaties kleiner wordt. Een belangrijke ondersteunende studie voor het belang van moderne technieken en beperkte doelgebieden is de studie van Fogh et al, waarbij re-irradiatie van recidief HGG werd uitgevoerd in 147 patiënten met behulp van hypofractionering met stereotactische precisie tot een mediane totale dosis van 35 Gy in fracties van 3,5 Gy. In deze studie werd uitsluitend het aankleurende gebied op de T1-contrast MRI als doelgebied gebruikt. Niet alleen toonde deze relatief grote studie een mediane overleving van tien tot elf maanden in zowel anaplastische gliomen als glioblastomen, maar werd er eveneens vrijwel geen graad ≥ 3 toxiciteit gezien (slechts in 1 patiënt behandeld met een dosis boven de 40 Gy) [Fogh 2010¹⁰⁰]. Bij de afweging of re-irradiatie een reële optie is, speelt naast de tumorlokatie ten opzichte van kritische normale organen, de definitie van de RTH doelgebieden, ook de grootte van het contrast-aankleurende gebied op de MRI een rol, waarbij er in de literatuur geen consensus is over de maximale grootte hiervan. In de praktijk blijkt men terughoudend te zijn bij re-irradiatie van een aankleurend tumorrecidief dat groter is dan 5 cm.

Wat betreft het optimale fractioneringsschema is geen goede aanbeveling te verkrijgen uit de literatuur. Niet-gerandomiseerde, veelal retrospectieve studies zijn gepubliceerd voor een enkele fractie radiochirurgie, extreme of minder extreme hypofractionering, of conventioneel gefractioneerde (stereotactische) schema's met uiteenlopende doses, en de resultaten hiervan zijn over het algemeen vergelijkbaar, evenals de toxiciteit. Een vergelijkende studie tussen deze radiotherapie technieken ontbreekt echter, zodat het niet goed mogelijk is een aanbeveling te doen. Een aantal studies rapporteren over de toepassing van brachytherapie (meestal ¹²⁵I of ¹⁹²Ir), met eveneens wisselende resultaten en toxiciteit [Amichetti 2011⁵]. Het risico op (symptomatische) radionecrose waarvoor reresectie noodzakelijk blijkt te zijn wordt zeer wisselend gerapporteerd voor de verschillende behandelingen, maar kan oplopen tot 31% [Amichetti 2011⁵]. Herbestraling met ge(hypo)fractioneerde stereotactische radiotherapie werd in een aantal series gecombineerd met chemotherapie, meestal temozolamide. Hoewel ook dit niet gerandomiseerd werd vergeleken, verbeterde de toevoeging van chemotherapie de overleving niet ten opzichte van radiotherapie alleen [Amichetti 2011⁵, Fogh 2010¹⁰⁰].

Chemotherapie/systeemtherapie bij hooggradig glioom

Deze submodule is onderverdeeld in de volgende sub-submodules:

- Chemotherapie nieuw gediagnostiseerd anaplastisch glioom
- Chemotherapie recidief anaplastisch glioom
- Chemotherapie nieuw gediagnostiseerd glioblastoom
- Chemotherapie recidief glioblastoom

Chemotherapie nieuw gediagnostiseerd anaplastisch glioom

Uitgangsvraag

Wat is de indicatie voor chemotherapie bij een patiënt met een nieuw gediagnostiseerd anaplastisch glioom?

Aanbeveling

Patiënten met een anaplastisch glioom met een 1p/19q-deletie dienen post-operatief behandeld te worden met radiotherapie (zie module Indicatie radiotherapie anaplastisch glioom) gevolgd door zes kuren PCV, volgens het EORTC-26951-protocol.

Er wordt geadviseerd, in afwachting van de resultaten van de EORTC-26053-studie (CATNON), patiënten met een anaplastisch glioom zonder gecombineerde 1p/19q-deletie te behandelen met postoperatieve radiotherapie alleen.

Bij te verwachten grote neurotoxiciteit van radiotherapie door een zeer groot doelvolume zou overwogen kunnen worden te kiezen voor temozolamide als postoperatieve behandeling bij anaplastische gliomen zonder 1p/19q-deletie [Wick 2009³⁸⁶].

Overwegingen

Bij te verwachten grote neurotoxiciteit van radiotherapie door een zeer groot doelvolume zou overwogen kunnen worden te kiezen voor temozolamide als postoperatieve behandeling bij anaplastische gliomen zonder 1p/19q-deletie [Wick 2009³⁸⁶].

Onderbouwing

Conclusies

Bij anaplastische gliomen met een 1p/19q-deletie is een verlenging van de overleving aangetoond, door PCV chemotherapie aan de radiotherapie toe te voegen.

Van den Bent 2013³⁵¹, Cairncross 2013⁴¹

Er zijn aanwijzingen dat er geen verschil is in progressievrije overleving tussen nabehandeling met monotherapie radiotherapie, PCV of TMZ.

Wick 2009³⁸⁶

Samenvatting literatuur

Chemotherapie voorafgaand aan resectie (neoadjuvant)

Er zijn geen data die het toevoegen van chemotherapie voorafgaand aan een resectie, met als doel de tumor kleiner te maken zodat een betere resectie kan worden verkregen, ondersteunen.

Adjuvante chemotherapie (= aanvullende chemotherapie direct na resectie) al dan niet in combinatie met radiotherapie, zonder dat er op de scan sprake is van tumorprogressie.

Oligodendrogliale tumoren zijn gevoeliger voor chemotherapie dan tumoren die geen oligodendrogliale

kenmerken hebben. De waarde van adjuvante chemotherapie voor patiënten met een 1p/19q-deletie werd aangetoond in zowel de EORTC-26951 [van den Bent 2013³⁵¹] als de RTOG-9402 [Cairncross 2013⁴¹] studie. In de EORTC-26951 zijn 368 patiënten geïncludeerd met anaplastisch oligodendroglioom en gemengd anaplastisch oligoastrocytoom (ten minste 25% oligodendrogliale-component) die werden gerandomiseerd tussen radiotherapie (RT) en RT plus 6 kuren procarbazine, lomustine en vincristine (PCV). In 2006 werd na een mediane follow-up van 5 jaar een verschil in progressievrije overleving (PFS) gevonden, echter geen statistisch significant verschil in overleving [Van den Bent 2006³⁵²]. Na langere follow-up bleek echter dat de overleving in de RT/PCV-arm significant langer was; 42.3 vs. 30.6 maanden in de RT-arm ([HR] 0,75; 95%CI 0,60-0,95). Ook kwamen data beschikbaar over de 1p/19q-status van patiënten. Voor de patiënten met een 1p/19q-deletie werd een mediane PFS van 157 vs. 50 maanden voor de gecombineerde behandeling ten opzichte van RT alleen gevonden, en een trend naar verbeterde totale overleving (OS) (mediaan niet bereikt vs. 112 maanden (HR 0,56; 95%CI 0,31-1,03)).

In de RTOG-9402 werden 291 patiënten met anaplastisch oligodendrocytoom en anaplastisch oligoastrocytoom gerandomiseerd tussen vier cycli intensified PCV met een hogere dosering lomustine, namelijk 130 mg/m² i.p.v. 110 mg/m² op dag 1 en zonder dosisbeperking per gift vincristine (de doses van de verschillende middelen waren niet gelijk aan die van de EORTC-26951) gevuld door RT vs. RT alleen. Voor patiënten met een 1p/19q-deletie werd een overlevingswinst gevonden (mediaan 14,7 versus 7,3 jaar, HR 0,59; 95%CI 0,37-0,95) in de gecombineerde behandelingsarm. In de groep patiënten zonder 1p/19q-verlies werd geen voordeel van gecombineerde behandeling gevonden (2,6 versus 2,7 jaar). Daarnaast lijkt er op basis van deze studie een voordeel voor de patiënten waarbij de tumor geen 1p/19q-deletie bevat maar wel een IDH1/2-mutatie voor PCV gevuld door RT. Dit betreft echter een post-hoc analyse bij een relatief kleine subgroep van 66 patiënten.

De NOA-4-studie is een gerandomiseerde fase III-studie bij patiënten met een anaplastisch glioom die als postoperatieve behandeling 2:1:1 RT (arm A) ten opzichte PCV (arm B1) vs. temozolamide (TMZ) (arm B2) heeft vergeleken [Wick 2009³⁸⁶]. Patiënten die in eerste instantie behandeld waren met postoperatieve radiotherapie (arm A), werden bij onacceptabele toxiciteit of progressie opnieuw gerandomiseerd tussen chemotherapie alleen met TMZ of PCV (arm B1 of B2). Andersom werden patiënten die direct chemotherapeutisch behandeld waren, na progressieve ziekte behandeld middels RT (arm A). Er werden 274 patiënten geïncludeerd, waarbij geen verschil tussen de behandelarmen werd gevonden voor het primaire eindpunt van de studie: gemiddelde (mediane) tijd tot progressieve ziekte. Voor geen van de subgroepen anaplastisch astrocytoom, anaplastisch oligodendrocytoom of anaplastisch oligoastrocytoom was een van de behandelarmen superieur. Er was geen verschil in progressievrije overleving tussen de patiënten die behandeld werden met TMZ ten opzichte van PCV. Het is van belang om te vermelden dat deze patiënten niet gerandomiseerd zijn op basis van 1p/19q-status van het anaplastische glioom. Ten tijde van rapportage waren de resultaten voor overleving nog immatuur. In het licht van de nagekomen rapportages bij studies EORTC 26951, RTOG 9402 en RTOG 8502 waarbij pas op lange follow-up algemene overleving significante verschillen ten voordele van toevoeging PCV kuren liet zien, dienen we mogelijk bedacht te zijn op een dergelijk nakomend bericht in deze studie.

Er is nog een retrospectieve studie met 109 patiënten [Brandes 2006^a²⁹] met een anaplastisch astrocytoom beschikbaar die achteraf het verschil tussen PCV (49 patiënten) en TMZ (60 patiënten) heeft geanalyseerd. Ook in deze analyse werd geen verschil in behandeluitkomst tussen de twee chemotherapieregimes gevonden.

In 2014 loopteen grote gerandomiseerde fase III-trial voor anaplastische glioompatiënten zonder 1p/19q deletie (CATNON, EORTC-26053). Dit is een 4-armige studie: RT alleen vs. RT plus concomitant temozolamide vs. RT plus adjuvant temozolamide vs. RT plus concomitant en adjuvant temozolamide. Aanvankelijk liep ook een gerandomiseerde fase III-trial voor patienten met 1p/19q-deletie (CO_DEL, EORTC-26081). Dit was een 3-armige studie waarbij een van de armen radiotherapie alleen was. Na het beschikbaar komen van de lange termijndata van zowel de EORTC-26951 als de RTOG-9402, werd RT alleen echter als onderbehandeling gezien en is de studie gesloten.
