Chemotherapie recidief anaplastisch glioom

Uitgangsvraag

Wat is de indicatie voor chemotherapie bij een patiënt met een recidief anaplastisch glioom?

Aanbeveling

Patiënten met een recidief hooggradig glioom dienen in een multidisciplinair neuro-oncologisch overleg besproken te worden. In de recidiefsetting dienen andere palliatieve behandelingen, zoals radiotherapie en chirurgie, telkens mede in overweging genomen te worden.

De werkgroep is van mening dat patiënten met een recidief anaplastisch glioom bij voorkeur in studieverband behandeld moeten worden.

Indien er geen studie beschikbaar is, wordt geadviseerd behandeling met twaalf kuren temozolamide te overwegen. Vervolgbehandeling met PCV lijkt vooral voor tumoren met een 1p/19q-deletie voor de hand te liggen.

Overwegingen

In de recidiefsetting dienen alle palliatieve behandelingen waaronder radiotherapie en chirurgie telkens mede in overweging genomen te worden.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat zowel PCV als temozolamide effectief kan zijn in zowel eerste als tweedelijnsbehandeling van het recidief anaplastisch glioom.

Yung 1999⁴⁰⁷, Brandes 2006²⁹, Van den Bent 2003³⁵⁸, Van den Bent 1998³⁵⁶, Brandes 2004³¹, Kouwenhoven 2006¹⁸²

Samenvatting literatuur

Er zijn meerdere studies die de waarde van chemotherapie bij het recidief anaplastisch glioom ondersteunen, zowel in de eerste als in de tweede lijn. Deze data zijn er voor zowel temozolamide [Yung 1999⁴⁰⁷, Brandes 2006²⁹, van den Bent 2003³⁵⁸] als PCV [van den Bent 1998³⁵⁶, Brandes 2004³¹, Kouwenhoven 2006¹⁸²] in verscheidende fase II-studies met patiënten aantal variërend van 18-97. Prognose en respons op chemotherapie is afhankelijk van de tijd tot recidief, histologie, moleculaire achtergrond en eerdere behandeling. Bij ongeveer de helft van deze patiënten wordt een objectieve response rate gezien met een progressievrije overleving na zes maanden van rond de 60% en na twaalf maanden van ongeveer 50%. In een tweedelijnsbehandeling liggen deze getallen lager [Yung 1999⁴⁰⁷, van den Bent 2003³⁵⁸, van den Bent 2001³⁵⁵, Triebels 2004³⁴⁴, Chinot 2001⁵⁷].

Chemotherapie nieuw gediagnostiseerd glioblastoom

Uitgangsvraag

Wat is de indicatie voor chemotherapie bij een patiënt met een nieuw gediagnostiseerd glioblastoom?

Aanbeveling

Bij patiënten met een glioblastoom in goede conditie tot 60 jaar dient postoperatief radiotherapie gegeven te worden, gecombineerd met concomitant en adjuvant temozolomide.

Voor de behandeling van patiënten met een glioblastoom ouder dan 60 jaar die niet fit genoeg zijn om deze behandeling te ondergaan wordt verwezen naar de module Behandeling van ouderen.

De chemotherapie dient gegeven te worden, door middel van temozolomide 75 mg/m²/d gedurende zes weken, gecombineerd met radiotherapie tot een totale dosis van 60 Gy in 30 fracties, gevolgd door een rustperiode van vier weken en daarna zes postradiatielijken temozolomide 200 mg/m²/d dag 1-5 elke vier weken. De eerste postradiatielukuur wordt gedoseerd op 150 mg/m²/d en opeenvolgende kuren worden vervolgens op 200 mg/m²/d gedoseerd indien goed verdragen. Dose-dense schema's van temozolomide hebben geen toegevoegde waarde voor het glioblastoom. Ook het toevoegen van bevacizumab aan het Stupp-schema laat geen toename in overleving zien.

De werkgroep is van mening dat bij goede en voortgaande tumorrespons overwogen kan worden het aantal postradiatielijken uit te breiden van zes naar twaalf.

Overwegingen

Op farmacologische gronden kan getwijfeld worden aan de noodzaak tot reduceren van de dosis van de eerste postradiatielukuur. Overwogen kan worden om de eerste postradiatielukuur ook op de dosis 200 mg/m²/d toe te dienen. In uitzonderlijke gevallen (enkel bij goede tolerantie en voortdurende tumorrespons met in achtneming dat het wetenschappelijk bewijs zeer beperkt is) kan de behandelaar overwegen het aantal postradiatielijken op te hogen tot maximaal twaalf. Er is een risico op pneumocystis jirovecii pneumonie tijdens de chemoradiatie. Overweeg profylaxe [De Vos 2013⁷⁵]. Bij 20-30% patiënten behandelde met chemoradiatie wordt pseudoprogressie waargenomen [Wen 2010³⁸²].

Onderbouwing

Conclusies

Er is aangetoond dat bij patiënten met een nieuw gediagnostiseerd glioblastoom en in een goede conditie chemoradiatie door middel van temozolomide resulteert in een langere overleving dan radiotherapie alleen. Stupp 2005³³¹, Stupp 2009³³⁰

De werkgroep is van mening dat het veilig is om het aantal postradiatielijken bij zeer goede tumorrespons uit te breiden. Door de opzet van de studies kan echter geen uitspraak worden gedaan over een mogelijk overlevingsvoordeel.

--- ---

Hau 2007¹³⁰, Roldan 2012²⁸¹

Het is aangetoond dat toevoeging van bevacizumab aan het Stupp-schema niet leidt tot verlenging van de totale overleving.

Chinot 2014⁵⁸, Gilbert 2014¹⁰⁹

Samenvatting literatuur

In 2005 werd een open gerandomiseerde fase III-onderzoek gepubliceerd verricht bij patiënten met een nieuw-gediagnostiseerd glioblastoom waarmee de aanvullende waarde van temozolamide aan (postoperatieve) radiotherapie werd aangetoond [Stupp 2005³³¹]. In de studie werden 573 volwassen patiënten tot 70 jaar (84% voorafgaande resectie, 16% alleen biopsie) gerandomiseerd tussen radiotherapie alleen of een gecombineerde behandeling met tegelijkertijd radiotherapie en temozolamide gevolgd door een behandeling met alleen temozolamide [Stupp 2005³³¹]. Het primaire eindpunt was overleving en dit werd geanalyseerd volgens het intention-to-treat-principe. De mediane overleving was 14,6 maanden in de gecombineerde radio- en chemotherapiegroep en 12,1 maanden in de groep die alleen werd behandeld met radiotherapie. Dit is een significant verschil, maar de grootte van het effect is gering. Na twee jaar waren echter 30 (10,4%) patiënten in de radiotherapiegroep en 76 (26,5%) patiënten in de combinatiegroep in leven, ook een significant verschil [Stupp 2005³³¹]. Na vijf jaar waren respectievelijk 5 (1,9%) en 28 (9,8%) patiënten in de radiotherapie- en combinatiegroep nog in leven [Stupp 2009³³⁰]. Een post-hoc analyse van 206 patiënten suggereerde dat patiënten met een gemethyleerd DNA-herstelenzym O6-methylguanine-DNA methyltransferase (MGMT) (aanwezig bij 45% van de onderzochte patiënten) een groter voordeel bij de toevoeging van temozolamide aan radiotherapie hebben [Hegi 2005¹³²]. De methyleringsstatus van MGMT heeft zowel een prognostische als predictieve waarde (Hegi 2005; Wick 2012). Bij chemoradiatie bleek het overlevingsvoordeel beduidend groter te zijn dan monotherapie radiotherapie bij patiënten met een gemethyleerde MGMT promotor. Dit voordeel is veel kleiner bij patiënten met een ongemethyleerde MGMT promotor. In geval dat de patiënt onvoldoende conditie heeft tot het verkrijgen van chemoradiatie, kan op basis van deze methyleringsstatus geopteerd worden tussen een van beide monotherapiën (dus ofwel radiotherapie ofwel chemotherapie). Of het uitbreiden van het aantal postradiatiekuren zinvol is, is niet bekend; het is vooral retrospectief beschreven. De enige prospectieve studie waarin een uitgebreid Stupp-schema (meer dan zes postradiatiekuren temozolamide) wordt onderzocht, bevatte ook graad III gliomen waardoor de mediane overleving van 58 maanden beïnvloed werd [Hau 2007¹³⁰].

Retrospectief Canadees onderzoek bij 52 patiënten laat zien dat 29 patiënten die met meer dan zes postradiatiekuren werden behandeld een mediane overleving van 24,6 maanden hadden versus 16,5 maanden bij een behandeling van zes postradiatiekuren. Doordat dit een retrospectieve studieopzet was, is er dan ook sprake van enige patiëntselectie-bias, aangezien zij met een betere respons op temozolamide ook langer overleven [Roldan 2012²⁸¹]. MGMT-status was geen doorslaggevende factor bij het besluit al dan niet te continueren na zes postradiatiekuren. Er moet wel gewezen worden op de beperkingen van deze studie: retrospectief, niet gekeken naar impact van type neurochirurgische ingreep of MGMT-status.

Daarnaast is er onderzoek verricht naar de dosis temozolamide, waarbij de gedachte is dat een hogere dosis leidt tot het teniet doen van de MGMT-gemedieerde resistentie. In een fasellII-studie werden 833 patiënten gerandomiseerd in een arm met postradiatie temozolamide standaarddosering 200 mg/m2/d d1-5 versus dose-dense schema 75 mg/m2/d d1-21 elke 4 weken in 6-12 cycli [Gilbert 2013¹¹⁰]. Deze studie liet geen significante verbetering van totale overleving (OS) zien (16,6 versus 14,9 maanden), noch van mediane

progressie vrije overleving (PFS) (5,5 versus 6,7 maanden). Echter, bij de MGMT-gemethyleerde groep werd wel significant verbeterde OS en PFS gezien, ongeacht het regimen temozolomide (algemene overleving: 21,2 versus 14 maanden voor de standaarddosering temozolomidegroep versus dose-dense temozolomidegroep, en progressievrije overleving: 8,7 versus 5,7 maanden voor de standaarddosering temozolomidegroep versus dose-dense temozolomidegroep). Per behandelarm werd in de MGMT-gemethyleerde groep geen significant verschil gevonden: OS 20,2 vs. 21,4 maanden en PFS van 6,5 vs. 10,1 maanden, respectievelijk in de standaard behandelarm en in de dose-dense behandelarm. Daarnaast werd een forse toename aan graad 3 toxiciteit gezien met name lymfocytopenie en vermoeidheid in de dose-dense arm ten opzichte van de standaardarm (53% versus 34%).

In een volgende studie werd gekeken naar de waarde van het postoperatief plaatsen van gliadel rasters (ook carmustine implants genoemd) in de resectieholte [Bock 2010²¹]. Bij 44 patiënten met nieuw gediagnostiseerd glioblastoom werden na het verwijderen van de tumor biologisch afbreekbare rasters geïmpregneerd met carmustine in het tumorbed geïmplanteerd. Hierna volgde chemoradiatie met temozolomide. Er werd geen beduidende overlevingswinst gezien met een mediane progressievrije overleving van 7 maanden en een mediane overleving van 12,7 maanden en daarbij werd een toename in toxiciteit gerapporteerd [Sabel 2008²⁸]. In een systematische review, die 19 studies met 795 patiënten samenvat, is de eventuele toegevoegde waarde van carmustine implants onderzocht. Hieruit bleek dat de overlevingswinst marginaal was, terwijl er een hoog risico op postoperatieve complicaties van 42,7% werd beschreven [Bregy 2013³²]. Gerandomiseerd fase III-onderzoek over de toevoeging van carmustine implants bij patiënten tijdens het Stupp-protocol ontbreekt.

Er is veel belangstelling voor de behandeling van glioblastomen met geneesmiddelen die de signaaltransductie via VEGF remmen, zoals bevacizumab, een monoklonaal antilichaam tegen VEGF. In een gerandomiseerde studie waarin de toevoeging van bevacizumab aan het Stupp-protocol werd onderzocht, werd bij 921 patiënten een mediane PFS van 10,6 maanden in de bevacizumabgroep versus 6,2 maanden in de placebogroep waargenomen. Deze significante verbetering vertaalde zich echter niet in overlevingswinst (resp. 16,8 versus 16,7 maanden). Een kwaliteit van leven-analyse toonde voorts dat het langer duurde voordat een toename in klachten optrad in de bevacizumabgroep (hazard ratio 0,64; 95%CI 0,56-0,74). Ook bleek er een grotere groep patiënten die de deelname startten met corticosteroïden-gebruik deze tijdens behandeling te kunnen staken indien ze behandeld werden met bevacizumab (66,3% versus 47,1%) [Chinot 2014[239]]. In een gelijkwaardige Amerikaanse studie met 978 patiënten, vertaalde een significant voordeel in PFS voor patiënten die met bevacizumab behandeld werden (10,7 versus 7,3 maanden) [Gilbert 2014¹⁰⁹]. Daarnaast liet deze studie een snellere achteruitgang in neurocognitie zien in de bevacizumabgroep. De onderzoekers duiden dit als vroegtijdige tumorprogressie dan wel bevacizumab-gerelateerde neurotoxiciteit.

Blokkade van integrines $\alpha\beta 3$ en $\alpha\beta 5$ door cilengitide werd onderzocht bij patiënten met glioblastomen in een fase III-onderzoek [Reardon 2008²⁷³], Stupp 2013³³³]. In deze gerandomiseerde studie werd de toevoeging van cilengitide aan het Stupp-protocol onderzocht bij 272 patiënten met nieuw gediagnostiseerde glioblastoom en gemethyleerde MGMT status. De mediane overleving was 26,3 maanden in beide armen met hazard ratio 1,02 (95%CI; 0,81-1,29). Mediane PFS was niet significant verschillend (13,5 maanden in de cilengitidearm en 10,7 maanden in de controle-arm). Enkelarmige fase II-studies waarbij nieuwe medicijnen aan het Stupp-protocol werden toegevoegd, melden een mediane overleving tussen 17 en 25 maanden, vergeleken met historische controles [Grossman 2009¹¹⁷], Butowski 2009³⁹], Soffietti

2014³²¹]. Hier kunnen echter, gezien het gebrek aan sluitend fase III-gerandomiseerd onderzoek, nog geen conclusies aan verbonden worden.

ICT-107 is een autologe dendritische cel vaccin met klasse I peptiden afkomstig van tumor-geassocieerde antigenen met overexpressie op gliomen [Phuphanich 2013²⁶⁰]. Een placebo-gecontroleerde, gerandomiseerde fase II- studie heeft het beoogde patiëntenaantal voor inclusie in 2013 bereikt.

Rindopepimut (CDX-110) induceert tumorspecifieke immuunrespons in tumoren met een epidermale groeifactor receptor vIII (EGFRvIII) mutatie [Babu 2012⁶]. In 2013 is een gerandomiseerde fase III-studie (ACT-IV/EORTC-26112) geopend met het streven 700 patiënten te includeren met een nieuwe gediagnostiseerde glioblastoom met EGFRvIII mutatie. Tot slot, NovoTTF-100A is een op de behaarde hoofdhuid draagbaar toedieningstoestel dat met afwisselende electrogebieden door middel van lage intensiteit tumorceldeling onderbreekt [Davies 2013⁶⁹]. Dit toestel is door de Food and Drug Administration (FDA) goedgekeurd. Deze goedkeuring slaat op de veiligheidsaspecten in kader van de toepasbaarheid van het toestel en niet de effectiviteit van de behandeling d.m.v. het toestel welke tot op heden niet is aangetoond bij het nieuw gediagnostiseerde glioblastoom [Salzberg 2008²⁹⁰]. In 2013 is er een studie gestart (Effect of NovoTTF-100A together with temozolamide in newly diagnosed glioblastoma multiforme (GBM). ClinicalTrials.gov Identifier NTC00916409).

Chemotherapie recidief glioblastoom

Uitgangsvraag

Wat is de rol van chemotherapie bij een patiënt met een recidief glioblastoom?

Aanbeveling

Bij een patiënt met een recidief glioblastoom in een goede conditie dient in eerste instantie een behandeling in studieverband te worden overwogen. Bij het niet beschikbaar of geschikt zijn voor een studie, dient in multidisciplinaire bespreking de verschillende behandelopties te worden besproken.

Als chemotherapeutische behandeling het advies is bij een aangetoond recidief glioblastoom zes maanden of meer na beëindigen van het Stupp-schema, kan temozolamide 200 mg/m²/d op dagen 1-5 elke vier weken overwogen worden.

Indien patiënten eerder behandeld zijn geweest met chemotherapie, wordt de eerste kuur gedoseerd op 150 mg/m²/d en worden opeenvolgende kuren vervolgens hoger gedoseerd, indien het goed wordt verdragen.

In het licht van de RESCUE studie kan dose dense temozolamide overwogen worden bij geselecteerde patiënten met een vroeg recidief glioblastoom en weinig doorgemaakte toxiciteit tijdens Stupp-schema.

Indien het recidief al tijdens of binnen zes maanden na staken Stupp-schema wordt aangetoond, is afhankelijk van de conditie van de patiënt PCV-kuren dan wel lomustine monotherapie een optie.

Behandeling met biologicals gebeurt in studieverband.

Overwegingen

Bij 20-30% van de patiënten behandeld met chemoradiatie wordt pseudoprogressie waargenomen [Wen 2010³⁸²]. Dit kan een rol spelen in de beoordeling van het effect van een vervolgbehandeling en benadrukt de noodzaak van een ervaren neuro-radioloog binnen het multidisciplinaire team.

Nadat er een recidief is vastgesteld, is de eerste keuze voor patiënten met een recidief glioblastoom een behandeling binnen studieverband. Er is geen gerandomiseerde studie die de verschillende behandelingsmodaliteiten (her-operatie, her-bestraling of tweedelijnschemotherapie/andere systeemtherapie) naast elkaar heeft bestudeerd en heeft vergeleken. Voor een adequate palliatieve behandeling buiten studieverband voor patiënten met een recidief glioblastoom is het belangrijk verschillende individuele patiëntgebonden factoren, zoals leeftijd, klinische conditie, mate van initiële resectie, respons op eerdere therapie, tijd sinds diagnose, of het een lokaal of diffuus recidief betreft, in acht te nemen. Gezien de beschikbaarheid van meerdere behandelingsmodaliteiten, dient bespreking in een neuro-oncologisch MDO plaats te vinden.

Onderbouwing

Conclusies

Het is aangetoond dat monotherapie temozolomide bij recidief glioblastoom effectief kan zijn, maar de kans op en de duur van het effect zijn niet zo groot (ca. 20% progressievrij na zes maanden wanneer geen eerdere behandeling met temozolomide is gegeven).

Er zijn (beperkte) aanwijzingen dat, in geval van een recidief na eerstelijns behandeling met (radiotherapie en) temozolomide, temozolomide opnieuw effectief kan zijn; de kans op effect lijkt groter wanneer het behandelings-vrije interval groter is.

Brada 2010²⁶, Wick 2009³⁸⁶, Perry 2008²⁵⁸, Perry 2010²⁵⁵

Er zijn aanwijzingen dat op nitrosurea gebaseerde therapie als tweedelijnstherapie bij recidief glioblastoom in geselecteerde patiëntengroepen een behandeloptie kan zijn.

Kuhnhenn 2012¹⁸⁵, Schmidt 2006³⁰⁰, Wick 2010³⁸⁸

Er zijn aanwijzingen dat bevacizumab gecombineerd met lomustine bij recidief glioblastoom een aanvulling in het behandelplan zou kunnen zijn. Bevestiging is nodig in een gerandomiseerde fase-III studie.

Taal 2014³³⁵

Samenvatting literatuur

Cytostatica

Temozolomide

In een niet-geblindeerd, gerandomiseerd fase II onderzoek werd temozolomide vergeleken met procarbazine bij 225 patiënten met een eerste recidief glioblastoom na operatie en radiotherapie [Yung 2000⁴⁰⁶]. De progressievrije overleving na zes maanden was significant hoger met temozolomide dan procarbazine (21% versus 8%). Een niet-geblindeerd, gerandomiseerd fase III-onderzoek waarbij temozolomide of PCV (procarbazine-lomustine-vincristine) werd gegeven aan patiënten met recidief graad III en IV glioom (n=447), die niet eerder met chemotherapie waren behandeld, liet geen verschil zien in mediane progressievrije overleving en algemene overleving (respectievelijk, 3,6 versus 4,7 maanden en 6,7 versus 7,2 maanden) [Brada 2010²⁶].

Dose-dense schema's temozolomide

In een fase III-studie werden twee doseringen van temozolomide gebruikt: een geregistreerde dosering temozolomide (200 mg/m² dag 1-5 elke vier weken) of een off-label intensieve dosering (100 mg/m² dag 1-21 elke 4 weken) [Brada 2010²⁶]. Hierbij bleek er een duidelijk voordeel in kwaliteit van leven voor patiënten behandeld met standaarddosering temozolomide ten opzichte van dose-dense therapie. Daarnaast werd er ook minder toxiciteit in de vijfdaagse temozolomide behandelde groep vermeld. Echter, hierbij moet in acht genomen worden dat de patiënten chemotherapie-naïef waren, omdat de studie plaatsvond voordat het Stupp-protocol standaardbehandeling voor nieuw gedagnosticeerde glioblastomen werd. Retrospectieve studies naar verscheidende rechallenge doseringsschema's met temozolomide bij recidief gliomen lieten een bescheiden winst voor dose-dense schema's zien met een 6 maanden progressievrije overleving variërend van 28 - 57% [Wick 2009³⁸⁶, Perry 2008²⁵⁸]. De uitkomst van de rechallenge behandeling werd gunstig beïnvloed naarmate de tijd tussen eerstelijnsbehandeling en vaststellen tumorprogressie groter werd.

Dit resulteerde in de Fase II RESCUE-studie waarbij recidief glioblastoom progressief na temozolomide monotherapie behandeld werd met een continuumschema [Perry 2010²⁵⁵]. Dit leidde tot 24% 6-maanden PFS bij

91 patiënten. Interessant is dat bij de groep met een vroegtijdig recidief (PD tijdens de eerste zes postradiatierecuren) vergelijkbare overlevingsresultaten behaald werden ten opzichte van de groep met laattijdig recidief (PD tijdens de zevende tot twaalfde postradiatierecuren) in vergelijking met de groep die recidiveerde na meer dan twee maanden na staken postradiatierecuren. Er was verschil in 6-maanden PFS (respectievelijk, 27,3 versus 7,4 versus 35,7%, p=0,0027) en in 1-jaars overleving (27,3 versus 14,8 versus 28,6%, niet significant). Hierbij werd rekening gehouden met de mogelijke invloed van pseudoprogressie, door patiënten met PD binnen twaalf weken na beëindigen chemoradiatie te excluderen. De onderzoekers konden geen verklaring vinden voor het verschil in overlevingsdata en vermoedden depletie van MGMT of een antiangiogenetisch effect van het dose-dense toedieningsschema. In een gelijkwaardige studie werd een 6-maanden PFS van 19% met een totale overleving van 7 maanden bij 37 patiënten waargenomen. Eerdere behandeling met bevacizumab leidde tot een lagere totale overleving (4 versus 13 maanden), maar dit kwam doordat de bevacizumab voorbehandelde patiëntengroep meerdere behandellijnen voorafgaand aan de behandeling met dose-dense temozolamide hadden gekregen. [Omuro 2013²³⁸]. Deze fase II-studie waarin een dose-dense schema temozolamide bij recidief glioblastoma werd onderzocht in het bevacizumab-tijdperk toonde aan dat de mediane overleving na recidief bij eerdere bevacizumab behandeling significant minder is dan bij bevacizumab-naïeve patiënten (13 versus 4,3 maanden met hazard ratio 3,1). Hierbij werd een objectiveerbare respons bij twee patiënten gezien met een 6-PFS van 29%. Echter, een review over dose-dens temozolamide schema's duidt op de verhoogde kans op lymfocytopenie gerelateerde *Pneumocystis jirovecii* pneumonie in vergelijking met standaarddosering [Neyns 2010²²⁷].

Combinatiebehandelingen met temozolamide

Een review toonde aan dat combinaties van temozolamide met cisplatine, fotemustine, interferon, sorafenib, celecoxib, irinotecan of PCV kuren geen verbetering in overleving gaf ten opzichte van standaard temozolamide monotherapie [Weller 2013³⁷⁸]. De toevoeging van tamoxifen 80 mg/m2/d aan temozolamide 75-150 mg/m2 op dagen 1-7 elke 2 weken werd in een fase II-studie bij 32 patiënten als tweedelinsttherapie geëvalueerd [Di Cristofori 2013⁸⁰]. De mediane totale overleving en progressie vrije overleving waren respectievelijk 17,5 en 7 maanden. Aangetoond is dat mismatch mutaties of hypermethylation van de promotor regio van MSH6, een DNA-herstelmechanisme, frequent voorkomt bij recidief glioblastoom [Yip 2009⁴⁰¹]. Hierdoor komen vaker DNA-fouten voor, die niet hersteld worden en hangt de overleving van de cel meer af van het PARP-herstelmechanisme. Vandaar dat PARP-inhibitoren als nieuwe behandelstrategie worden onderzocht om de efficiëntie van temozolamide te verhogen.

Nitrosurea (carmustine of lomustine)

Nitrosurea-gebaseerde kuren bij recidief glioblastoom na eerdere temozolamide behandeling toonde bij 69 patiënten een beperkte mediane progressie vrije overleving van 15 weken aan, met een partiële remissie bij 1 patiënt [Kuhnhenn 2012¹⁸⁵]. Bij 86 patiënten met een recidief glioblastoom werden drie partiële remissies en een mediane progressie vrije overleving gezien van 17,1 weken na PCV-kuren [Schmidt 2006³⁰⁰]. Lomustine monotherapie bij 92 patiënten met een, met temozolamide behandeld, recidief glioblastoom, toonde in een fase III-studie een 19% 6-PFS en een mediane totale overleving van 7 maanden [Wick 2010³⁸⁸].

Irinotecan

Irinotecan in recidiefsetting bij patiënten met een glioblastoom toonde geen respons bij alle 40 onderzochte patiënten en is dus geen alternatieve behandeling bij een recidief [Chamberlain 2002⁴⁹].

Nieuwe middelen

Bevacizumab

Op grond van een gerandomiseerd fase II onderzoek bij 170 patiënten, waarin bevacizumab werd vergeleken met de combinatie bevacizumab en irinotecan, is bevacizumab in de VS geregistreerd (conditional approval) voor gebruik bij glioblastoom recidieven [Friedman 2009¹⁰³]. De respons ratio was hoger dan verwacht: 53% in de combinatie-arm, 43% in de bevacizumab-arm versus 10% bij historische controles. Echter, overlevingsvoordeel was minder duidelijk met een mediane overleving van acht maanden, vergeleken met zes maanden bij historische controles. Het ontbreken van een controlegroep zonder bevacizumab was voor de European Medicines Agency reden om dezelfde registratieaanvraag af te wijzen. Een bijkomende complicerende factor is dat bevacizumab pseudorespons in de hand werkt, door een effectieve therapie tegen hersenoedeem te zijn en de bloedhersenbarriëre te sluiten waardoor aankleuring afneemt [Omuro 2007²⁴⁰]. In de gerandomiseerde Nederlandse fase II-studie BELOB [acroniem: Bevacizumab vs. bevacizumab plus lomustine vs. lomustine bij recidief GBM] werden drie behandelarmen met elkaar vergeleken: bevacizumab, lomustine en lomustine in combinatie met bevacizumab bij 148 patiënten met recidief glioblastoom [Taal 2014³³⁵]. In de combinatie-arm werd de dosering lomustine verlaagd van 110 naar 90 mg/m² op dag 1 elke 6 weken, wegens beenmergsuppressie. Na 9 maanden was de OS 38% in de bevacizumab-arm, 43% in de lomustine-arm, 59% in de combinatie-arm met lomustine 90 mg/m² en 88% in de combinatie-arm met lomustine 110 mg/m². Op deze bevinding is de studie EORTC- 26101 aangepast naar een fase IIItwee-arms-studie waarin lomustine monotherapie vergeleken wordt met de combinatie lomustine en bevacizumab bij eerste recidief na Stupp-protocol.

Tot nu toe is er enkel retrospectief onderzocht of het zinvol is bevacizumab te continueren bij progressie onder bevacizumab [Reardon 2012²⁷²]. Toevoeging van fotemustine, sorafenib, temsirolimus, combinatie carboplatine-irinotecan, dose-dense schema temozolamide, interferon- en combinatie cetuximab-irinotecan aan bevacizumab in de recidiefsetting gaf geen verbeterde overleving [Soffieti 2014³²¹, Galanis 2013¹⁰⁴, Lassen 2013¹⁹³, Desjardins 2012⁷⁸, Groves 2009¹¹⁸, Hasselbach 2010¹²⁹].

Enzastaurine en cediranib

In een gerandomiseerde fase III-studie werd lomustine monotherapie vergeleken met enzastaurine bij 266 patiënten met recidief glioblastoom na eerdere temozolamide behandeling [Wick 2010³⁸⁸]. Het onderzoek werd voortijdig stopgezet bij een geprotocolleerde interim-analyse vanwege onvoldoende werkzaamheid. Op dat moment was er geen significant verschil in het primaire eindpunt: het percentage patiënten dat progressievrij was na zes maanden (11 versus 19%, respectievelijk enzastaurine en lomustine). Onderzoekers verklaarden het niet aantonen van effectiviteit door een te vroeg opstarten van de fase III-studie zonder de definitieve resultaten van de fase II-studie te hebben afgewacht. In een drie-arms fase III REGAL-studie werd cediranib, een VEGF-receptor inhibitor, onderzocht ten opzichte van lomustine en de combinatie van beide agentia [Batchelor 2013¹¹]. Bij 325 patiënten met een glioblastoom die vooraf met het Stupp-protocol behandeld waren, werd geen significant verschil gezien in PFS tussen de drie behandelarmen, waarbij de hazard ratio bij de combinatie-arm 0,76 met 95%CI 0,53-1,08 bedroeg. Mogelijk ligt nog onvoldoende kennis van predictieve factoren aan de grondslag van het falen van deze studie.

Nieuwe toedieningswegen: NovoTTF-100A, CED en gliadel rasters

NovoTTF-100A werd in een gerandomiseerde fase III-studie onderzocht bij 237 patiënten in vergelijking met

een behandeling naar keuze van de behandelaar. Na een mediaan van twee lijnen therapie voorbehandeling werd een mediane overleving van 6.6 versus 6 maanden waargenomen [Butowski 2013⁴⁰, Stupp 2012³³³]. Toevoeging van gliadel rasters in een recidiefsetting geeft geen noemenswaardige overlevingswinst [De Bonis 2012⁷³]. Een systematische review liet slechts bij een selecte groep patiënten in recidiefsetting, waarbij een haast complete resectie van het recidief werd verkregen, enige overlevingswinst zien [Perry 2007²⁵⁶]. De PRECISE-studie was een fase III-studie die convection-enhanced delivery (CED) van cintredekin besudotox vergeleek met gliadel rasters [Kunwar 2010¹⁸⁶]. Dit toeleveringssysteem omzeilt de bloed-hersenbarrièrè via een druk-gedreven infusieflow, waarbij een recombinant eiwit bestaande uit interleukine-13 en een gemuteerde vorm van Pseudomonas toxine werd toegediend. Ondanks het feit dat IL-13-receptoren overvloedig in glioblastoom aanwezig zijn, werd geen significante overlevingswinst aangetoond. Of CED met andere middelen effectief kan zijn, is onvoldoende bekend; het wordt in diverse studies onderzocht.

Noodzaak voor verder onderzoek

Het niet kunnen aantonen van effectiviteit bij verschillende fase III-studies bij recidief (en nieuw gediagnostiseerd) glioblastoom heeft geleid tot hernieuwd preklinisch en translationeel onderzoek [Yin 2013³⁹⁸]. Het glioblastoom wordt onderverdeeld in verschillende histologische subklassen op basis van genetisch profiel en moleculaire diagnostiek [Colman 2008⁶³, Verhaak 2010³⁶⁵]. Epidermale groeifactor (EGF) en de receptor EGFR, platelet-derived groeifactor (PDGF) A en B en de receptoren PDGFR α en β, vasculair endotheliale groeifactor (VEGF) en de receptor VEGFR, insuline-like groeifactor-1 (IGF-1) en de receptor (IGFR), transforming groeifactor-α (TGF-α), fibroblast groeifactor (FGF) en hepatocytair groeifactor (HGF) spelen een grote rol binnen het tumorproces bij het glioblastoom. Stimulering van deze receptoren stuurt drie grote cascadeprocessen aan: mitogen-activated proteïne kinase (MAPK); fosfoïnositide 3 kinase (PI3K/Akt); en fosfolipase Cγ (PLCγ) en proteïne kinase C (PKC). Deze processen reguleren celdeling, differentiatie en voorkomen apoptose. Hierop richt zich het klinisch onderzoek naar de ontwikkeling van doelgerichte therapie. Dit heeft geleid tot een reeks fase II-studies waarin verschillende klassen 'biologicals', tyrosine kinase remmers en antilichamen zijn en worden onderzocht [Weller 2013³⁷⁸, Quant 2010²⁶⁷]. Het falen van een fase III-studie waarin imatinib, een PDGFR inhibitor, gecombineerd met hydroxyurea, een ribonucleotide reductase remmer, werd onderzocht in vergelijking met hydroxyurea alleen, werd door onderzoekers verklaard vanwege een gebrek aan kennis van moleculaire en genetische karakteristieken [Dreseman 2010⁸³]. Hoewel beide agentia in monotherapie geen effect lieten zien, leek een eerdere fase II-studie met combinatiebehandeling overlevingswinst aan te tonen [Reardon 2005²⁷¹].

Behandeling van ouderen bij glioblastoom

Uitgangsvraag

Wat is de beste behandeling voor oudere patiënten met een glioblastoom?

Aanbeveling

Bij oudere patiënten (> 60 jaar) in slechte conditie (KPS < 70 ;) en met cognitieve functiestoornissen (MMSE $< 27/30$) is de levensverwachting $\leq 4-5$ maanden en lijkt de beperkte potentiële overlevingswinst van behandeling niet op te wegen tegen de belasting van de behandeling. De werkgroep is van mening dat in deze groep afzien van behandeling een realistische optie is.

Bij patiënten van 60-70 jaar, bij wie het behandelteam verwacht dat chemoradiatie volgens het Stupp-protocol te zwaar uitvalt (bijvoorbeeld door comorbiditeit, minder goede conditie en/of afwijkende MMSE), is de werkgroep van mening dat MGMT-promotoranalyse ingezet kan worden. Bij gemethyleerde promotor wordt de patiënt dan monotherapie met temozolamide aangeraden, bij een niet gemethyleerde promotor een kort schema radiotherapie. Er is een risico op een foutpositieve uitslag van de MGMT-promotormethylering waardoor voor een individuele patiënt het weglaten van radiotherapie zou kunnen betekenen dat hem/haar een effectieve behandeling wordt onthouden.

Bij patiënten ouder dan 70 jaar wordt geadviseerd MGMT-promotoranalyse in te zetten. Bij een gemethyleerde promotor wordt de patiënt dan monotherapie met temozolamide aangeraden, bij een niet gemethyleerde promotor een kort schema radiotherapie. Slechts in uitzonderlijke gevallen (zeer goede conditie en MMSE én resectie ondergaan én geen comorbiditeit) kan het behandelteam overwegen om in overleg met de patiënt alsnog chemoradiatie volgens het Stupp-protocol toe te dienen.

Overwegingen

In het algemeen leidt behandeling van het glioblastoom met radiotherapie en/of chemotherapie niet tot verbetering van de klinische toestand, wel mogelijk tot verlenging van de overleving. De klinische conditie en levenskwaliteit van de patiënt op het moment van aanvang van de behandeling bepalen daarom in sterke mate of en op welke manier de patiënt behandeld dient te worden. Diverse geriatrische beoordelingsschalen zijn onderzocht in de oncologie en kunnen wellicht aanvullende informatie geven betreffende prognose, maar de toegevoegde waarde hiervan staat niet vast [Puts 2014²⁶⁶. Leeftijd is een belangrijke prognostische factor en gemiddeld hebben oudere patiënten een slechtere prognose dan jongere patiënten, hoewel oudere patiënten met overigens gunstige prognostische factoren ook baat kunnen hebben van intensieve behandeling. Over de leeftijd waarop een patiënt oud of ouder is, bestaat geen consensus en ook in studies worden verschillende leeftijden aangehouden. Doorgaans wordt met 'ouder' een leeftijd bedoeld vanaf 60 tot 70 jaar.

Bij patiënten tot 70 jaar is de meerwaarde van gecombineerde bestraling en temozolamide chemotherapie aangetoond. Bij oudere patiënten is alleen monotherapie bestraling vergeleken met monotherapie temozolamide. Combinatiebehandeling bij ouderen, met een kort schema radiotherapie gecombineerd met

temozolomide, is onderzocht in de EORTC/NCIC-ouderenstudie maar hiervan zijn de resultaten nog niet bekend. Eventueel kan in afwachting van de resultaten van deze studie bij oudere patiënten met een gemethyleerde MGMT promotor ook temozolomide met een kort schema radiotherapie worden overwogen.

Onderbouwing

Conclusies

Het is aangetoond dat bij oudere patiënten (> 60 jaar) in slechte conditie (KPS < 70) en/of met cognitieve functiestoornissen (MMSE $< 27/30$) de levensverwachting kort is ($\leq 4-5$ maanden).

Curran 1993⁶⁵, Mirimanoff 2006²²⁰, Stupp 2009³³⁰

Het is aannemelijk dat bij oudere patiënten (> 60 jaar) in slechte conditie (KPS < 70) en/of met cognitieve functiestoornissen (MMSE $< 27/30$) de beperkte potentiële overlevingswinst van de behandeling niet opweegt tegen de belasting van de behandeling.

Roa 2004²⁷⁹, Slotman 1996³¹⁷, McAleese 2003²¹²

Het is aannemelijk dat voor patiënten van 60-70 jaar met gunstige prognostische factoren (goede performance status, KPS > 70 én MMSE $\geq 27/30$ én resectie ondergaan) behandeling met standaard 60 Gy radiotherapie met gelijktijdig en adjuvant temozolomide zinvol kan zijn. Voor deze groep geldt dat de mediane overleving langer is dan 12 maanden en dat bij hen, evenals bij jongere patiënten, de kans op levensverlenging met standaard 60Gy gecombineerde chemoradiotherapie groter is dan bij radiotherapie alleen.

Stupp 2009³³⁰, Stupp 2005³³¹, Yin 2013³⁹⁸

Het is aangetoond dat de methyleringsstatus van de MGMT-promotor bij oudere patiënten ($> 60-65$ jaar) predictieve waarde heeft ten aanzien van behandeling met temozolomide.

Malmstrom 2012²⁰⁸, Yin 2014a/b³⁹⁷ 400

Het is aannemelijk dat een lang schema radiotherapie geen voordeel biedt boven een kort schema bij oudere patiënten.

Roa 2004²⁷⁹, Malmstrom 2012²⁰⁸

Het is aannemelijk dat bij patiënten vanaf 60-65 jaar, in geval van een gemethyleerde promotor, temozolomide chemotherapie tenminste gelijkwaardig is aan bestraling.

Malmstrom 2012²⁰⁸, Wick 2012³⁸⁷, Yin 2014³⁹⁷

Het is aannemelijk dat ook oudere patiënten in een suboptimale conditie temozolomide chemotherapie kunnen verdragen.

Gallego Perez-Larraya 2011¹⁰⁵

Het is aangetoond dat de bepaling van de methyleringsstatus van de MGMT-promotor geen volmaakte sensitiviteit en specificiteit heeft. Er is een risico op een foutpositieve uitslag van de MGMT-

promotormethylering waardoor voor een individuele patiënt het weglaten van radiotherapie zou kunnen betekenen dat hem/haar een effectieve behandeling wordt onthouden.

Quillien 2012²⁶⁸, Vlassenbroeck 2008³⁶⁷

Samenvatting literatuur

De prognose voor oudere patiënten met een glioblastoom is slechter dan voor jonge patiënten, zeker wanneer de algehele conditie of mentale status verminderd is. Het is de vraag of standaardbehandeling met radiotherapie en gelijktijdig en adjuvant temozolamide haalbaar en zinvol is bij deze patiëntenpopulatie [Curran 1993⁶⁵, Mirimanoff 2006²²⁰, Stupp 2009³³⁰]. Bij aanwezigheid van de volgende prognostisch ongunstige variabelen; leeftijd > 60 jaar, Karnofsky performance status (KPS) < 70, MMSE < 27/30, niet hebben ondergaan van een resectie, wordt de prognose slechter en neemt de winst van aanvullende behandelingen af [Mirimanoff 2006²²⁰, Stupp 2009³³⁰]. Subgroepanalyses van de gerandomiseerde fase III-EORTC/NCIC-studie 26981, waarin behandeling met 60 Gy radiotherapie vergeleken werd met gecombineerd 60 Gy radiotherapie en temozolamide, laten echter zien dat ook bij oudere patiënten (60-70 jaar) met gunstige prognostische factoren (ruime resectie, goede performance status en MMSE > 27/30) de mediane overleving meer dan twaalf maanden is [Stupp 2009³³⁰, Stupp 2005³³¹]. In een prospectieve serie van 42 opeenvolgende patiënten ouder dan 65 jaar (mediaan 71,3 jaar) bleek deze behandeling haalbaar bij 70% van de patiënten, zonder behandelinggeïnduceerde toxiciteit, en was de prognose significant beter bij patiënten met een KPS ≥ 80% [Fiorica 2010⁹⁹]. Hoewel er geen andere gerandomiseerde studies beschikbaar zijn, ondersteunt een recente meta-analyse van niet gerandomiseerde studies overlevingswinst met deze behandeling ook voor patiënten ouder dan 65 jaar. In deze meta-analyse zijn ook patiënten boven de 80 jaar geïncludeerd en, overeenkomstig de subgroepanalyse van de EORTC-26981-studie, was de winst van de gecombineerde behandeling het grootste bij de patiënten met een goede performance status die een resectie hadden ondergaan [Yin 2013³⁹⁸]. Veel oudere patiënten zijn echter in een minder goede conditie of hebben geen resectie ondergaan, waardoor de prognose beduidend slechter is [Curran 1993⁶⁵, Chaichana 2011⁴⁷].

Om deze patiënten een acceptabele maar minder belastende behandeling te kunnen aanbieden is een aantal studies verricht. Behandeling met een kort schema radiotherapie is vergeleken met een lang schema (standaard, 60 Gy) in een gerandomiseerde studie bij 100 patiënten van 60 jaar of ouder. Er werd geen verschil gevonden in overleving na behandeling met 40 Gy in 15 fracties in vergelijking met 60 Gy in 30 fracties [Roa 2004²⁷⁹]. Enkele niet-gerandomiseerde studies toonden een vergelijkbaar resultaat met een mediane overleving van 4-6 maanden [Roa 2004²⁸⁰, Slotman 1996³¹⁷, McAleese 2003²¹²]. Behandeling met radiotherapie werd vergeleken met alleen ondersteunende therapie in een gerandomiseerde studie bij 85 patiënten van ≥ 70 jaar met een KPS van ≥ 70. Na alleen ondersteunende therapie werd een mediane overleving gevonden van 16,9 weken en na 50 Gy gefractioneerde radiotherapie was de mediane overleving 29,3 weken [Keime-Guibert 2007¹⁶⁶]. Oudere patiënten in een minder goede conditie (KPS < 70) zijn in deze studies niet geïncludeerd; wel bleek uit een fase II-studie met 70 patiënten dat deze populatie behandeling met temozolamide kan verdragen (13-14% neutro- en thrombopenie) en dat dit leidt tot een mediane overleving van 25 weken (95%CI 19 tot 28 weken) [Gallego Perez-Larraya 2011¹⁰⁵].

Of radiotherapie of temozolamide de voorkeur verdient bij oudere patiënten met een glioblastoom werd onderzocht in twee gerandomiseerde fase III-studies. In de Nordic-studie werden 342 patiënten van 60 jaar of

ouder gerandomiseerd voor behandeling met een kort schema radiotherapie (10 x 3.4 Gy), TMZ chemotherapie (tot 6 kuren, 200 mg/d op dag 1-5/28) of een standaardschema radiotherapie (30 x 2 Gy) [Malmstrom 2012²⁰⁸]. De overleving was langer voor patiënten die met temozolomide werden behandeld, dan met een lang schema radiotherapie (8,5 vs. 6 mnd.; hazard ratio [HR] 0·70; 95%CI 0·52-0·93, p=0·01). Bij patiënten boven de 70 jaar leidde bovendien een kort schema radiotherapie tot een langere overleving dan een lang schema radiotherapie. Van de patiënten die werden behandeld met temozolomide hadden degenen met een gemethyleerde MGMT-promotor een langere overleving dan die met een niet-gemethyleerde MGMT-promotor (9,7 maanden [95%CI 8,0-11,4] vs. 6,8 maanden [5,9-7,7]; HR 0,56 [95%CI 0,34-0,93], p=0·02) [Malmstrom 2012²⁰⁸]. In de NOA 08-studie werden 373 patiënten van 65 jaar of ouder gerandomiseerd tussen standaard radiotherapie (30 x 2 Gy) en dose-dense temozolomide (100 mg/m²/d op dag 1-7 en 15-21/28) [Wick 2012³⁸⁷]. Er was geen verschil in mediane overleving tussen de twee groepen, getest volgens non-inferiority principe: 8,6 mnd. (95%CI 7,3-10,2) in de TMZ-groep versus 9,6 mnd. (95%CI 8,2-10,8) in de radiotherapiegroep (hazard ratio [HR] 1,09; 95%CI 0,84-1,42, p-non-inferiority=0,033). Hoewel deze twee studies een verschillende dosering temozolomide gebruikten, is het niet waarschijnlijk dat dat de resultaten heeft beïnvloed: een gerandomiseerde fase III-studie toonde geen verschil in effectiviteit aan tussen adjuvant dose-dense temozolomide en adjuvante standaard dosering bij patiënten met een glioblastoom [Gilbert 2013¹¹⁰].

In deze studies is de combinatie van een kort schema radiotherapie met chemotherapie niet onderzocht; hiertoe is de EORTC/NCI-ouderenstudie (clinicaltrials.gov NCT00482677) opgezet, waarvan de inclusie compleet is maar de resultaten nog niet bekend zijn.

In een meta-analyses van studies naar radiotherapie en temozolomide bij oudere glioblastoompatiënten blijkt dat bij patiënten met gemethyleerde MGMT-promotor in hun tumor temozolomide effectiever was dan radiotherapie voor verbetering van de overleving (temozolomide vs. radiotherapie: HR 0,66; 95%CI 0,47-0,93) terwijl het tegenovergestelde gold voor patiënten met niet-gemethyleerde tumoren (HR 1,32; 95%CI 1,00-1,76) [Yin AA 2014a/b^{397 400}].

Hoewel in diverse studies MGMT-promotormethylering voorspellend was voor effectiviteit van temozolomide is de praktijk van de bepaling niet eenvoudig. Diverse methodes voor het onderzoeken van de methyleringsstatus zijn in gebruik en de uitslagen van de verschillende methodes voor individuele patiënten zijn lang niet altijd in overeenstemming met elkaar [Quillien 2012²⁶⁸]. Bovendien bepaalt de keuze van het afkappunt of de test een hogere sensitiviteit of specificiteit zal hebben [Vlassenbroeck 2008³⁶⁷].

Indicatie geriatrisch assessment

Uitgangsvraag

Bij welke patiënten met een middels pathologie bevestigd glioom en een indicatie voor behandeling is een geriatrisch assessment geïndiceerd?

Aanbeveling

Verzamel zoveel mogelijk informatie die relevant is om de winst en risico's van de verschillende behandel mogelijkheden op korte en lange termijn zo goed mogelijk in te schatten evenals de levensverwachting en kwaliteit van leven met en zonder behandeling. Betrek hierbij eventueel de huisarts. Inventariseer aanvullend samen met de patiënt en/of naaste(n) de levensvisie, beleving en persoonlijke behandel doelen van de patiënt met een middels pathologie bewezen glioom.

Overweeg een geriater, of verpleegkundig specialist geriatrie te betrekken indien er sprake is van één of meerdere van onderstaande factoren:

- aanwijzingen voor kwetsbaarheid, aan de hand van een screeningsinstrument (bijvoorbeeld de 'geriatric 8' aangevuld met MMSE of 6CIT voor het in kaart brengen van cognitief functioneren),
- uitgebreide comorbiditeit met het risico op behandelcomplicaties (bijv. meer toxiciteit),
- polyfarmacie met risico van interacties met bijvoorbeeld chemotherapie,
- KPS tussen 60 en 70,
- twijfel bij behandelteam en/of patiënt/naasten over meest geschikte behandeling,
- twijfel over de wilsbekwaamheid van de patiënt.

Maak de definitieve behandelkeuze in samenspraak met patiënt en diens naaste(n).

Overwegingen

Het doel van deze uitgangsvraag was om te achterhalen of het uitvoeren van een geriatrisch assessment bij oudere (kwetsbare) patiënten tot betere uitkomsten leidt, dan wanneer een geriatrisch assessment niet is uitgevoerd. Hiervoor is geen literatuur gevonden. Daarom kunnen er op basis van systematisch gevonden literatuur geen conclusies getrokken worden, en worden de aanbevelingen onderbouwd in de overwegingen.

Voor- en nadelen van de interventie en de kwaliteit van het bewijs

Het IDH wildtype glioblastoom, WHO graad 4, is de meest voorkomende primaire hersentumor bij volwassenen, zeker bij ouderen. Hogere leeftijd is zowel een negatieve prognostische factor als ook een risicofactor voor het optreden van bijwerkingen/toxiciteit van behandeling. Dit kan een nadelige invloed hebben op de kwaliteit van leven. De groep oudere patiënten is meer heterogeen dan de jongere patiëntengroep, waarbij rekening gehouden moet worden met comorbiditeit, fysiek en cognitief functioneren en mate van zelfredzaamheid. Derhalve zijn de biologische leeftijd en fitheid belangrijker gebleken dan kalenderleeftijd. (Balducci, 2005; Colloca, 2020) Indien de fitheid van de oudere patiënt niet correct wordt ingeschat, bestaat het risico van onder- of overbehandeling, met als gevolg afname van kwaliteit van leven.

In diverse studies wordt gerefereerd aan Balducci (Balducci, 2005), die oudere oncologische patiënten indeelt

in 3 categorieën: de zogenoemde Balducci 1 zijn de fitte ouderen die volledig zelfredzaam zijn zonder comorbiditeit. Deze groep kan meestal dezelfde behandeling ondergaan als jongere patiënten. De tweede categorie (Balducci 2) is de 'kwetsbare oudere', met 1-2 comorbiditeiten en/of beperkingen in ADL. Bij deze groep patiënten zal de (standaard)behandeling moeten worden aangepast. De derde groep (Balducci 3) of "unfit elderly", betreft patiënten die 3 of meer comorbiditeiten hebben, ADL afhankelijk zijn, of een progressief geriatrisch syndroom hebben. Bij deze groep lijkt de beperkte potentiële overlevingswinst van behandeling niet op te wegen tegen de belasting van de behandeling.

Momenteel wordt fitheid – naast anamnese van patiënt en naaste(n) – vastgesteld met behulp van de Karnofsky Performance Scale (KPS), European Organization for Research and Treatment of Cancer (EORTC) classificatie van de WHO en Mini-Mental State Examination (MMSE). Dit zijn echter breed screenende instrumenten die niet specifiek ontwikkeld zijn voor de neuro-oncologische patiënt.

Bij neuro-oncologische patiënten is het belangrijk de beoordeling van de cognitie mee te nemen in het vaststellen van eventuele behandelopties. Cognitieve stoornissen hebben namelijk invloed op de therapietrouw en de toxiciteit gerelateerd aan behandeling en daardoor op het vroegtijdig staken van behandeling (Colloca, 2020). Cognitieve stoornissen kunnen derhalve als negatieve prognostische factor worden beschouwd. Cognitieve stoornissen kunnen ook van invloed zijn op de wilsbekwaamheid van een patiënt (kan de patiënt zelf een adequate beslissing nemen ten aanzien van wel/geen behandeling en begrijpt hij/zij de consequenties van zijn/haar keuze).

De gouden standaard om fitheid en kwetsbaarheid te beoordelen is een geriatrisch assessment, ook wel 'Comprehensive Geriatric Assessment' (CGA) genoemd. Het belangrijkste doel van zo'n CGA is het voorkomen of vertragen van functionele achteruitgang. In de Nederlandse richtlijn 'Comprehensive Geriatric Assessment 2021' wordt aanbevolen om een risico-inschatting te maken op het risico op negatieve uitkomsten als er behandeling wordt overwogen met een hoog risico op complicaties en/of functionele achteruitgang, er potentieel beperkte opbrengst te verwachten is of wanneer er twijfel is over de belastbaarheid van de patiënt. Omdat het uitvoeren van een CGA door een klinisch geriater arbeidsintensief is, is het raadzaam om de patiënten te selecteren die baat kunnen hebben bij een CGA. Dit kan gebeuren aan de hand van meetinstrumenten, waaronder de VMS-vragen (veiligheidsmanagementsysteem) of de G8 ('Geriatric 8') vragenlijst. Deze laatste vragenlijst is het meest gevalideerde screeningsinstrument binnen de oncologische populatie. De G8 vragenlijst is speciaal ontwikkeld voor de oudere kankerpatiënt en heeft een sensitiviteit van > 80% in 6 studies en een specificiteit van > 60% in 4 studies (Bruijnen, 2020). De vragenlijst bestaat uit 8 vragen: afname van voedingsinname, gewichtsverlies, mobiliteit, neuropsychologische problemen, BMI, polyfarmacie, inschatting eigen gezondheidstoestand en leeftijd (Bruijnen, 2020). De totale score bedraagt 17 en de score is afwijkend indien deze ≤ 14 is. De afname duurt ongeveer 2 minuten. Een beperking van de vragenlijst is de beperkte aandacht voor cognitieve problemen, welke – zoals hierboven reeds vermeld – een belangrijk aspect zijn voor de prognose van de neuro-oncologische patiënt. Er wordt derhalve geadviseerd om additioneel een MMSE of 6CIT af te nemen (richtlijn CGA).

Wanneer een patiënt vanuit de G8 mogelijk kwetsbaar is gebleken, kan worden overwogen een patiënt naar de geriater of internist ouderengeneeskunde te verwijzen voor een uitgebreidere beoordeling. Deze uitgebreidere beoordeling bestaat uit tenminste de volgende onderdelen : anamnese en hetero-anamnese

ten aanzien van mate van zelfredzaamheid, voedingsstatus, vallen en mobiliteit, sociale omstandigheden, steunsysteem, cognitieve en wel stemmingsstoornissen en eerder doorgemaakt delier. Naast voorgenomen aspecten moet er aandacht zijn voor de wensen en verwachtingen van de patiënt zelf. Het doel van de beoordeling wordt omschreven als: het formuleren van een conclusie met betrekking tot geriatrische kwetsbaarheid en de invloed daarvan op beleid/behandeltraject.

Hamaker (2018) verrichtte een systematische review naar het effect van een geriatrisch evaluatie op de oncologische en niet-oncologische behandeling van ouderen (> 70 jaar) met kanker en is dus niet specifiek gericht op onze populatie. Daarbij werden 36 publicaties uit 35 studies geïncludeerd. Bij mediaan 28% (spreiding 8 tot 45%) van de oudere patiënten met kanker werd op basis van de gegevens van de geriatrische evaluatie het oncologische behandelplan aangepast. Daarnaast werd in mediaan 72% van de patiënten (spreiding 26 tot 100%) één of meer niet-oncologische interventies ingezet gericht op het verbeteren van de uitgangspositie van de patiënt. Het uiteindelijke effect op de behandeluitkomsten was wisselend, waarbij vaker de ingestelde behandeling kon worden gegeven (positief effect in 75% van de studies) en er minder behandelings-gerelateerde complicaties of toxiciteit optrad (positief effect in 55% van de studies).

Hoewel er geen vergelijkende studies zijn gevonden over de meerwaarde van geriatrische assessments bij oudere patiënten met een glioblastoom zijn er in de afgelopen jaren wel diverse studies gedaan naar de inzetbaarheid en het effect van screeningslijsten en assessments bij deze patiënten. Dit vanuit een behoefte aan verbetering van de wijze waarop voor oudere patiënten de behandelkeuze wordt gemaakt. Het geriatrische assessment (CGA) is in deze studies het meest onderzochte/gebruikte en (waarschijnlijk) het meest aanbevolen instrument. Ook in neuro-oncologische centra waar geriatrische beoordeling wordt ingezet bij glioblastoom patiënten bij wie er twijfel is over de optimale behandeling blijkt dat een geriatrisch assessment kan bijdragen om tot een weloverwogen behandelkeuze te komen.

Waarden en voorkeuren van patiënten (en evt. hun naasten/ mantelzorgers)

Patiënten met een behandelwens hebben vaak tot doel om tijd van leven te verlengen met behoud van kwaliteit van leven, zodat ze de dingen kunnen blijven doen die voor hen belangrijk zijn. Hiervoor is een zo passend mogelijke behandelkeuze van belang. Een extra consult bij een geriater (assessment) kost tijd en energie voor patiënt en naasten, maar kan wel helpend zijn in het behalen van het doel. Daarnaast kan dit consult aandachtspunten naar voren halen die bij de neurologische beoordeling onderbelicht zijn gebleven. Om te beoordelen of een patiënt gebaat kan zijn bij een dergelijke beoordeling kan gebruik gemaakt worden van een screeningsinstrument zoals de G8. Bij een vitale oudere patiënt zonder risicofactoren voor functionele achteruitgang heeft een uitgebreide geriatrische beoordeling geen meerwaarde, dit zal ook gelden voor een terminale patiënt.

Kosten (middelenbeslag)

Het inzetten van uitgebreide geriatrische assessments is arbeidsintensief en kost tijd. Hamaker et al (2018) hebben in hun systematische review laten zien dat een geriatrisch assessment wel inzichten ten aanzien van optimale behandel mogelijkheden kan opleveren, echter is er hierbij niet gekeken naar kosteneffectiviteit. De werkgroep acht het mogelijk dat door het voorkomen van overbehandeling extra consulten en ziekenhuisopnames beperkt worden.

Aanvaardbaarheid, haalbaarheid en implementatie

Het inzetten van arbeidsintensieve uitgebreide geriatrische assessments vraagt om voldoende capaciteit bij de afdeling geriatrie (geriater of verpleegkundig specialist) of de interne geneeskunde (met name internist ouderengeneeskunde) en het is de vraag of dat dit haalbaar is gezien de sterke vergrijzing en de daarmee toenemende incidentie van gliomen. Het is derhalve van groot belang de juiste groep patiënten te selecteren waarbij deze interventie meerwaarde zal hebben. Gezien de bevindingen uit de systematische review van Hamaker et al (2018) zal het bij vermoedelijk een kwart van de patiënten een verandering in behandelplan teweegbrengen en zit de grootste winst in het verbeteren van de uitgangspositie van de patiënt door niet-oncologische interventies.

Onderbouwing

Achtergrond

Vanwege toenemende vergrijzing zal de incidentie van gliomen de komende decennia verder stijgen, met name in de hogere leeftijdsgroepen. Patiënten met een hogere leeftijd zijn vaak ondervertegenwoordigd in wetenschappelijke studies en een optimale behandelstrategie ontbreekt derhalve in deze groep. Kalenderleeftijd komt vaak niet overeen met de biologische leeftijd van patiënten, waarbij kwetsbaarheid een belangrijke parameter is. Behoud van kwaliteit van leven en autonomie zijn belangrijk, vaak belangrijker dan verlengen van levensduur. In het algemeen leidt behandeling van het glioblastoom met radiotherapie en/of chemotherapie niet tot verbetering van de klinische toestand, wel mogelijk tot verlenging van de overleving. Het is derhalve belangrijk met de individuele patiënt te bespreken wat de wensen of behandeldoelen zijn. De klinische conditie en levenskwaliteit van de patiënt op het moment van aanvang van de behandeling bepalen daarom in sterke mate of en op welke manier de patiënt behandeld dient te worden. Het is onduidelijk of het zinvol is om een geriatrische evaluatie uit te voeren bij oudere patiënten die potentieel in aanmerking komen voor behandeling. Sommige instituten doen het wel, andere niet. Ook de aanpak en bij wie deze evaluatie wordt uitgevoerd verschilt.

Voor de tekst in deze module geldt dat waar 'geriater' geschreven staat, ook een verpleegkundig specialist geriatrie of internist ouderengeneeskunde gelezen kan worden.

Conclusies

All outcomes

No GRADE	No evidence was found regarding the effect of geriatric assessment on any outcome when compared with no geriatric assessment in elderly (frail) patients with glioma who are potentially eligible for treatment.
----------	--

Zoeken en selecteren

A systematic review of the literature was performed to answer the following question: Does a geriatric assessment in elderly (frail) patients with glioma lead to different outcomes?

Patients: Elderly (frail) patients (over 60 years old) with pathology confirmed glioma who are potentially

eligible for treatment

Intervention: Geriatric evaluation

Control: No geriatric evaluation

Outcomes: Treatment options, treatment related complications, complete treatment, survival, quality of life, patient satisfaction

Relevant outcome measures

The guideline development group considered quality of life and overall survival as a critical outcome measure for decision making; and treatment related complications, complete treatment, patient satisfaction, number of treatment options as an important outcome measure for decision making.

Treatment options: eligible for systemic therapy, radiotherapy and/or resection.

For the other outcomes, the working group did not define the outcome measures listed above but used the definitions used in the studies.

Per outcome, the working group defined the following differences as a minimal clinically (patient) important differences:

Overall survival: Benefit > 12 weeks or hazard ratio < 0.7

Quality of life: The minimum important difference (MID) has been estimated to be a difference of 0.08 or more points for the EQ-5D utility index, seven or more points for the EQ-5D VAS (Pickard, 2007), or ≥ 10 points on the Karnofsky Performance Score (KPS).

Cognitive functioning: MMSE ≥ 3 points, EORTC cognitive functioning subscale ≥ 10 points.

Adverse events: lethal < 5% (absolute difference), acute or severe < 25%.

Treatment options/treatment completemet: RR ≤ 0.8 or ≥ 1.25

Search and select (Methods)

The databases Medline (via OVID) and Embase (via Embase.com) were searched with relevant search terms until December 2nd 2021. The detailed search strategy is depicted under the tab Methods. The systematic literature search resulted in 52 hits. Studies were selected based on the following criteria:

- Systematic reviews (searched in at least two databases, and detailed search strategy, risk of bias assessment and results of individual studies available), randomized controlled trials, or observational comparative studies;
- Full-text English language publication;
- Studies including ≥ 20 (ten in each study arm) patients; and
- Studies according to the PICO

Five studies were initially selected based on title and abstract screening. After reading the full text, all studies were excluded (see the table with reasons for exclusion under the tab Methods), and no studies were included.

Results

No studies were included in the analysis of the literature.

Level of evidence of the literature

No studies were included in the analysis of the literature.

Behandeling ouderen/kwetsbaren

Uitgangsvraag

Met welke aandachtspunten dient rekening gehouden te worden specifiek in de behandeling van ouderen/kwetsbare patiënten met een glioblastoom?

Aanbeveling

Zie bij patiënten af van behandeling indien er sprake is van een Karnofsky performance status (KPS) < 70 of ernstige cognitieve functiestoornissen.

Bespreek de wensen en verwachtingen van de patiënt, de te verwachten therapeutische winst en de mogelijke nadelen van de behandelingen. Raadpleeg bij twijfel een geriater/verpleegkundig specialist geriatrie/internist ouderengeneeskunde conform de aanbevelingen in module 'Indicatie geriatrisch assessment'.

Bij patiënten met een behandelindicatie en wens tot behandeling:

- Bied bij patiënten boven 60 jaar ook chemoradiatie volgens het Perry protocol als alternatief voor het standaard Stupp protocol aan in afwezigheid van comorbiditeit/polyfarmacie met risico op behandelcomplicaties.
- Bied bij patiënten boven 60 jaar monotherapie op basis van MGMT-status aan (monotherapie temozolamide bij gemethyleerde MGMT-tumor en radiotherapie bij ongemethyleerde tumor) indien ze geen gecombineerde behandeling aankunnen door comorbiditeit of verhoogd risico op behandelcomplicaties.

Overwegingen

Het doel van deze uitgangsvraag was om te achterhalen wat de waarde van oncologische behandeling is bij oudere patiënten met een nieuw gediagnosticeerd glioblastoom is. Er is één Cochrane systematische review met netwerk meta-analyse gevonden die oncologische behandeling vergeleek met ondersteunende (palliatieve) zorg (Hanna, 2020). Naast enkele methodologische beperkingen waren de studiepopulaties relatief klein. Bewijskracht voor de kritieke uitkomstmaten (progressievrije overleving, totaaloverleving en kwaliteit van leven) was laag tot zeer laag. Dit betekent dat andere studies kunnen leiden tot nieuwe inzichten. Er kunnen op basis van de literatuur alleen geen sterke aanbevelingen geformuleerd worden over de toegevoegde waarde van oncologische behandeling voor oudere patiënten met nieuw gediagnosticeerde glioblastoom.

Voor- en nadelen van de interventie en de kwaliteit van het bewijs

Op basis van de studies door Mirimanoff (2006) en Stupp (2009) concludeert de werkgroep dat de prognose voor patiënten met een glioblastoom slechter is bij aanwezigheid van de volgende prognostisch ongunstige variabelen: leeftijd > 60 jaar, Karnofsky performance status (KPS) < 70, MMSE < 27/30, niet hebben

ondergaan van een resectie en afwezigheid van MGMT promotor hypermethyleatie. Met aanwezigheid van deze ongunstige variabelen wordt de prognose slechter en neemt de winst van aanvullende behandelingen af (Mirimanoff, 2006; Stupp, 2009).

In de beschreven meta-analyse van Hanna (2020) wordt een winst op overall survival (OS) beschreven bij het toedienen van chemoradiatie bij ouderen van 70 jaar. Subgroepanalyse naar leeftijdsgroepen of MGMT status was helaas niet mogelijk wegens onvoldoende beschikbare geaccumuleerde data (Hanna, 2020). In de studies waar wel MGMT data beschikbaar was, ziet de werkgroep een overlevingsvoordeel (Minniti, 2012; Perry, 2017). In de studie van Perry (2017) werden 562 patiënten gerandomiseerd tussen chemoradiatie of radiotherapie, 281 per behandelarm. De mediane totale overleving was langer met chemoradiatie dan met radiotherapie alleen (9,3 maanden vs. 7,6 maanden; hazard ratio (HR) voor overlijden, 0,67; 95% betrouwbaarheidsinterval (CI), 0,56 tot 0,80; $P<0,001$), evenals de mediane progressievrije overleving (5,3 maanden versus 3,9 maanden; hazard ratio voor ziekteprogressie of overlijden, 0,50; 95% BI, 0,41 tot 0,60; $P<0,001$). Bij 165 patiënten met MGMT gemethyleerde glioblastoom was de mediane totale overleving 13,5 maanden met chemoradiatie en 7,7 maanden met alleen radiotherapie (hazard ratio voor overlijden, 0,53; 95% BI: 0,38 tot 0,73; p -waarde $<0,001$). Kwaliteit van leven bleef onveranderd tussen beide groepen.

In de Nordic-studie werden 342 patiënten van 60 jaar of ouder gerandomiseerd voor behandeling met een kort schema radiotherapie ($10 \times 3,4$ Gy), temozolamide chemotherapy (tot 6 kuren, 200 mg/d op dag 1-5/28) of een standaardschema radiotherapie (30×2 Gy) (Malmstrom, 2012). De overleving was langer voor patiënten die met temozolamide werden behandeld, dan met een lang schema radiotherapie (8,5 vs. 6 mnd; hazard ratio [HR] 0,70; 95%BI: 0,52 tot 0,93, $p=0,01$). Bij patiënten boven de 70 jaar leidde bovendien een kort schema radiotherapie tot een langere overleving dan een lang schema radiotherapie. Van de patiënten die werden behandeld met temozolamide hadden degenen met een gemethyleerde MGMT- promotor een langere overleving dan die met een niet-gemethyleerde MGMT-promotor (9,7 maanden (95% BI: 8,0 tot 11,4) versus 6,8 maanden (5,9 tot 7,7); HR 0,56 (95%BI: 0,34 tot 0,93), p -waarde=0,02) (Malmstrom, 2012). In de NOA 08-studie werden 373 patiënten van 65 jaar of ouder gerandomiseerd tussen standaard radiotherapie (30×2 Gy) en dose-dense temozolamide (100 mg/m²/d op dag 1-7 en 15-21/28) (Wick, 2012). Er was geen verschil in mediane overleving tussen de twee groepen, getest volgens non-inferiority principe: 8,6 mnd. (95% BI: 7,3 to 10,2) in de TMZ-groep versus 9,6 mnd. (95%BI: 8,2 tot 10,8) in de radiotherapiegroep (HR 1,09; 95% BI: 0,84 tot 1,42, p -non-inferiority= 0,033). Zowel de NOA-08 als de Nordic studie zijn opgenomen in de meta-analyse door Hanna (2020), echter niet individueel uitgelicht. Hoewel deze twee studies een verschillende dosering temozolamide gebruikten, acht de werkgroep het niet waarschijnlijk dat dit de resultaten heeft beïnvloed: een gerandomiseerde fase III-studie toonde geen verschil in effectiviteit aan tussen adjuvant dose-dense temozolamide en adjuvante standaard dosering bij patiënten met een glioblastoom (Gilbert, 2013). Hypofractioneerde schema's zijn niet inferieur aan standaard bestralingsschema's volgens deze review (de Melo, 2020). De verminderde belasting in tijd en verminderd risico op bijwerkingen zijn argumenten ten voordele van hypofractionering.

In een meta-analyse van studies naar radiotherapie en temozolamide bij oudere glioblastoompatiënten blijkt dat bij patiënten met gemethyleerde MGMT-promotor in hun tumor temozolamide effectiever was dan radiotherapie voor verbetering van de overleving (temozolamide versus. radiotherapie: HR 0,66; 95%BI: 0,47

tot 0,93) terwijl het tegenovergestelde gold voor patiënten met niet-gemethyleerde tumoren (HR 1,32; 95%BI 1,00 tot 1,76) (Yin, 2014).

Mits goede selectie op basis van patiënt- en tumorkarakteristieken acht de werkgroep dat therapievoordelen (overleving en kwaliteit van leven) kunnen worden behaald zoals beschreven in meta-analyse (Nassiri, 2020).

Waarden en voorkeuren van patiënten (en evt. hun naasten/ mantelzorgers)

In de beslissing omtrent het te voeren beleid bij de oudere (>65 jaar), kwetsbare patiënt met een nieuw gediagnosticeerd glioblastoom, zal te allen tijde de waarden en voorkeuren van de patiënt worden meegenomen. Een belangrijk doel van een interventie is overlevingswinst met een acceptabele kwaliteit van leven. Kwaliteit van leven zal voor de individuele patiënt verschillende waarden omvatten. Interventie kan er echter ook voor zorgen dat de kwaliteit van leven achteruit gaat, bij de patiënt met een slechte initiële uitgangssituatie, op basis van bijvoorbeeld de klinische conditie. Ook kan de keuze voor een interventie zorgen voor frequente ziekenhuisbezoeken en dus extra belasting voor de patiënt opleveren. Dezen en andere voor- en nadelen van een bepaalde interventie zullen door de behandelaar met de patiënt besproken moeten worden waardoor er een weloverwogen afweging gemaakt kan worden of de belasting en impact van een interventie voldoende meerwaarde voor hen heeft, afgewogen tegen de te verwachten overlevingswinst en kwaliteit van leven (gedeelde besluitvorming).

Kosten (middelenbeslag)

Door patiënten beter te selecteren op behandelingen die haalbaar zijn op grond van objectieve parameters kunnen best mogelijk behandeling leiden tot minder zorgbelasting (minder bezoeken aan het ziekenhuis, minder bijwerkingen, kortere behandeltijd). Volgens de Dutch Brain Tumor Registry (DBTR) hebben 35% van de glioblastoompatiënten ouder dan 70 jaar in de periode 2014 – 2017 geen nabehandeling na operatie gehad. 25% had enkel radiotherapie, 10% enkel temozolamide monotherapie en 30% een vorm van gecombineerd schema. In dit rapport wordt geen gewag gemaakt over de overleving of levenskwaliteit per behandeltype in deze categorie patiënten. Het is dus realistisch aan te nemen dat 65% van de oudere patiënten na de diagnose een vorm van nabehandeling krijgt. Aangezien MGMT bepaling al standaard in het diagnose pakket zit voor deze leeftijdscategorie, kan in het multidisciplinair overleg beter worden ingespeeld op het type patiënt en tumor met een op maat gemaakte behandeling, leidend tot minder afgebroken behandelingen door bijwerkingen of progressie. Uitgaande van 40% kans op aantreffen MGMT gemethyleerde tumor, verwacht de werkgroep dat het aandeel nabehandelde patiënten met chemotherapie alleen zal stijgen naar 15 – 26%. Als we uitgaan dat de helft van de resterende patiënten chemoradiatie krijgt en de andere helft radiotherapie, komen beide groepen rond 20 – 25% aandeel uit. Een kleinere groep zal de gecombineerde behandeling krijgen, waarbij met een gehypofractioneerde schema men minder vaak naar het ziekenhuis zal hoeven komen en men meer patiënten met dezelfde middelen kan behandelen. Minder blootstelling aan zware behandelingsschema's leidt tot minder bijwerkingen en ziekenhuisopname. Kosten zullen volgens de werkgroep enigszins gereduceerd worden, maar omdat deze behandelvormen naast radiotherapie geen dure medicatie bevatten zal het qua besparing beperkt zijn.

Aanvaardbaarheid, haalbaarheid en implementatie

De randvoorwaarde is om leeftijd niet als een beperking te beschouwen, maar als een gegeven naast de overige prognostische factoren. Op basis van een volledig beeld gebaseerd op patiënt en tumorkarakteristieken kan een arts het gesprek met de patiënt starten waarin de mogelijkheden en uitdagingen liggen per behandeloptie in een proces van gedeelde besluitvoering. Gezien de soms beperkte winst in prognose is het van belang om altijd de optie symptoomgericht in plaats van tumorgericht handelen te bespreken. Bij twijfel kan de hulp van de huisarts voor context bepaling en van de geriater voor ondersteunende maatregelen tijdens behandelen ingeroepen worden.

Rationale van de aanbeveling: weging van argumenten voor en tegen de interventies

Over de leeftijd waarop een patiënt oud of ouder is, bestaat geen consensus en ook in studies worden verschillende leeftijden gehouden. Doorgaans wordt in de internationale literatuur met 'ouder' een leeftijd bedoeld vanaf 60 of 70 jaar.

Aan oudere patiënten met goede Karnofsky performance status (KPS) ≥ 70 , MMSE $\geq 27/30$ (indien verricht bij verdenking op cognitieve stoornissen), status na resectie en in aanwezigheid van MGMT-promotor hypermethylatie kan volgens de werkgroep een chemoradiatie schema volgens de studie van Perry (2017) worden aangeboden. Het betreft hypogefractioneerde bestraling van 15 sessies tot 40 Gy met gelijktijdig temozolamide 75 mg/m² gevolgd door zes postradiatiekuren temozolamide 200 mg/m² dagen 1-5 elke 4 weken. Voor oudere patiënten met een of meer ongunstige prognostische factoren, maar die volgens de eigen behandelaar wel nog in aanmerking voor aanvullende behandeling komen, kan op basis van MGMT-status monotherapie hypogefractioneerde radiotherapie (ongemethyleerde tumoren) of monotherapie temozolamide (gemethyleerde tumoren) met de patiënt en zijn naasten worden besproken. Naar analogie met de NOA-08 studie zou een maximale behandelduur met TMZ van één jaar een overweging kunnen zijn.

Onderbouwing

Achtergrond

In de huidige situatie zijn er nog onvoldoende handvatten over welke overwegingen leiden tot de keuze van het behandelbeleid bij de oudere (> 65 jaar oud) kwetsbare patiënt met een nieuw gediagnosticeerd glioblastoom, welke in voldoende conditie verkeert om potentieel in aanmerking te komen voor een behandeling. In verband met de vergrijzing van de bevolking zal deze vraag in de klinische praktijk steeds vaker aan de orde zijn. De werkgroep heeft een advies geformuleerd over de overwegingen die een rol kunnen spelen bij de keuze voor oncologische behandeling (bijvoorbeeld neurochirurgie, radiotherapie, chemoradiotherapie, systemische therapie (inclusief chemotherapy)) dan wel best supportive care in deze populatie.

Verdiepende informatie over de specifieke therapieën kunt u vinden in de betreffende modules, dat wil zeggen de informatie over resectie, chemotherapy en radiotherapie wordt beschreven in de modules behandeling hooggradig glioom, respectievelijk over neurochirurgie, radiotherapie en chemotherapy/systeemtherapie.

Conclusies

1.1 Progression free survival (critical)

Low GRADE	The evidence suggests radiotherapy increases progression free survival when compared with no treatment (supportive care) in elderly people with newly diagnosed glioblastoma. <i>Source: Hanna, 2020</i>
------------------	---

1.2 Overall survival (critical)

Very low GRADE	The evidence is very uncertain about the effect of RT40, RT60, CRT, RT40+BEV-CRT, BEV-CRT, or TMZ on overall survival compared with no treatment (supportive care) in elderly people with newly diagnosed glioblastoma. <i>Sources: Hanna, 2020</i>
-----------------------	--

2. Quality of life, any length of follow-up (critical)

Very low GRADE	The evidence is very uncertain about the effect of radiotherapy on quality of life, compared with no treatment (supportive care) in elderly people with newly diagnosed glioblastoma. <i>Sources: Hanna, 2020</i>
-----------------------	--

3. Adverse events (critical); 4. Objective response (important)

No GRADE	No information was found regarding the effect of oncological treatment on adverse events or objective response when compared with no treatment (best supportive care) in patients with newly diagnosed glioblastoma. <i>Source: -</i>
-----------------	--

5. Cognitive functioning, any length of follow-up (important)

Very low GRADE	The evidence is very uncertain about the effect of radiotherapy on cognitive functioning compared with no treatment (supportive care) in elderly people with newly diagnosed glioblastoma. <i>Sources: Hanna, 2020</i>
-----------------------	---

Comparison with neurosurgery

No GRADE	No information was found regarding the effect of neurosurgery on any outcome when compared with no treatment (best supportive care) in elderly patients with newly diagnosed glioblastoma. <i>Source: -</i>
-----------------	--

Samenvatting literatuur

Description of studies

The selection of Hanna (2020) was performed in April 2019. Twelve studies were included in the review. Studies either included only elderly (65+ years) or performed separate analyses on an elderly subgroup of patients. Participants had newly diagnosed glioblastoma, receiving interventions including best supportive care, hypofractionated radiotherapy, standard radiotherapy, temozolamide, chemoradiotherapy, bevacizumab with chemotherapy, and bevacizumab with radiotherapy. A network meta-analysis was performed for overall survival, using six studies. Other outcomes (progression free survival, health related quality of life and cognition) were reported for the comparison between radiotherapy (50 Gy) and supportive care, by Keime-Guibert (2007).

Table 1. Study characteristics

Study ID	Intervention (n)	RT EQD2 ab2/ab10	Control (n)	Age	Baseline KPS
Wirsching, 2018	RT 40.0 Gy (25)	48Gy/43Gy	BEV_RT 40.0 Gy (50)	Median 70 (range 65-87)	90-100: 41 (55%) 70-80: 27 (36%) ≥60: 7 (9%)
Saran, 2016	CRT (33)	60Gy/60Gy	BEV_CRT (39)	NR for subgroup	NR for subgroup

Malmstrom, 2012	TMZ (42)	60Gy/60Gy	RT 60.0 Gy (41)	Approx. median age: 70 (range 60-88)	NR for subgroups
		46Gy/38Gy	RT 34 Gy (40)		
Perry, 2017	RT 40.05 Gy (281)	48Gy/43Gy	CRT (281)	Approx. median age: 73 (range 65 to 90)	NR
Roa, 2004	RT 60.0 Gy (47)	60Gy/60Gy 48Gy/43Gy	RT 40.0 Gy (48)	RT 60: mean age 72.4 (SD: 5.4) RT 40: mean age 71.0 (SD: 5.5)	median 70 (IQR: 60-80)
Wick, 2012	RT 60.0 Gy (178)	60Gy/60Gy	TMZ (195)	RT 60: median 72 (range 66-84) TMZ: median 71 (range 66-82)	Median 80 (range 60-100)

Abbreviations: ab2: alpha/beta ratio for central nervous system tissue; ab10: alpha/beta ratio for tumor; BEV_(C)RT, bevacizumab (chemo)radiotherapy; CRT, Chemoradiotherapy; EQD2, equivalent dose in 2Gy based on the Linear Quadratic Model; KPS, Karnofsky Performance Score; NR, Not Reported; RT, Radiotherapy; TMZ, temozolomide IQR:

Results

1. Survival (critical)

1.1 Progression free survival - radiotherapy 50 Gy versus supportive care

The outcome progression free survival was analyzed by Keime-Guibert (2007). Median time to progression was 14.9 weeks (95% CI 10.9 to 22.1) in participants receiving radiotherapy with supportive care, and 5.4 weeks (95% CI 4.4 to 7.6) in participants receiving supportive care only. The corresponding hazard ratio for disease progression was 0.28 (95% CI 0.17 to 0.46). This difference was clinically relevant, favoring the group receiving radiotherapy with supportive care.

1.2 Overall survival – network meta-analysis

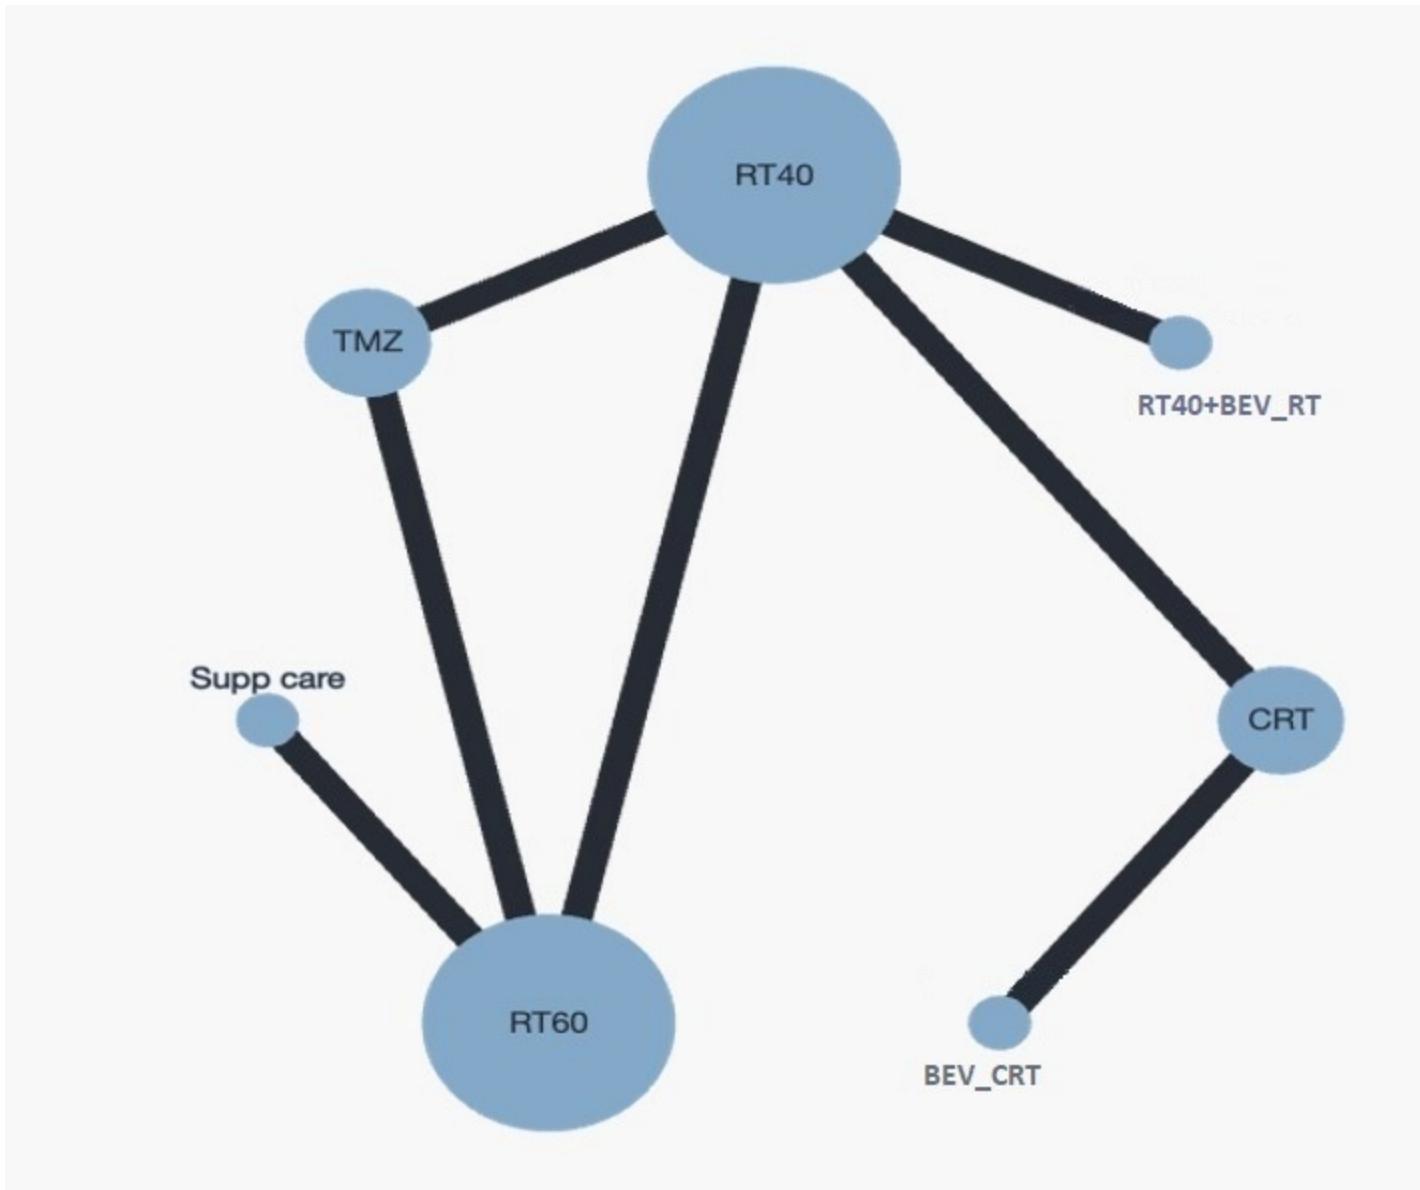

The outcome overall survival was analyzed in a network using a total of seven RCTs (Wirsching, 2018; Saran, 2016, Keime-Guibert, 2007; Malmstrom, 2012; Perry, 2017; Roa, 2004; and Wick, 2012). Network estimates for hazard ratios for overall survival are shown in table 2. The network is shown in figure 1.

Table 2. Network estimates for overall survival, reference supportive care only

Intervention (n)	Relative effect network meta-analysis, HR (95% CI)
Supportive care only (81)	1.0
RT 60.0 Gy (713)	0.47 (0.29 to 0.76)
BEV_RT (75)	0.48 (0.23 to 1.00)
RT 40.0 Gy (930)	0.44 (0.25 to 0.77)
TMZ (538)	0.42 (0.25 to 0.71)
CRT (635)	0.30 (0.17 to 0.53)
BEV_CRT (73)	0.25 (0.11 to 0.54)

Abbreviations: BEV_(C)RT, bevacizumab (chemo)radiotherapy; CRT, Chemoradiotherapy; RT, Radiotherapy; TMZ, temozolomide

Figure 1. Network plot for overall survival

2. Quality of life (critical) - radiotherapy 50 Gy versus supportive care

Health related quality of life was measured by Keime-Guibert (2007) at 30, 60, 90 and 135 days, using the European Organization for Research and Treatment of Cancer Quality of life Questionnaire (EORTC QLQ-C30) summary score (0-100), with higher scores indicating higher quality of life.

Quality of life (30 days)

At 30 days, mean quality of life in the group receiving radiotherapy with supportive care (n= 31) was 57.6 (SD 3.5). Mean quality of life in the group receiving supportive care (n= 28) was 61.8 (SD 4.7). This resulted in a mean difference of -4.2 (95% CI -6.33 to -2.07). This difference was not clinically relevant.

Quality of life (60 days)

At 60 days, mean quality of life in the group receiving radiotherapy with supportive care (n= 23) was 56.6 (SD 3.9). Mean quality of life in the group receiving supportive care (n= 22) was 60.3 (SD 5). This resulted in a mean difference of -4.7 (95% CI -7.33 to -2.07). This difference was not clinically relevant.

Quality of life (90 days)

At 90 days, mean quality of life in the group receiving radiotherapy with supportive care (n= 22) was 49.1 (SD 4). Mean quality of life in the group receiving supportive care (n= 17) was 56.7 (SD 6.3). This resulted in a mean difference of -7.6 (95% CI -11.03 to -4.17). This difference was not clinically relevant.

Quality of life (135 days)

At 135 days, mean quality of life in the group receiving radiotherapy with supportive care (n= 16) was 58.4 (SD 4.5). Mean quality of life in the group receiving supportive care (n= 10) was 48.1 (SD 6.7). This resulted in a mean difference of 10.7 (95% CI 6.01 to 15.39). This difference was clinically relevant.

3. Adverse events (critical)

None of the RCTs assessed the effect of oncological treatment compared with no treatment (best supportive care) in patients with newly diagnosed glioblastoma on adverse events.

4. Objective response (important)

None of the RCTs assessed the effect of oncological treatment compared with no treatment (best supportive care) in patients with newly diagnosed glioblastoma on objective response.

5. Cognitive functioning (important) - radiotherapy 50 Gy versus supportive care

Cognition was measured by Keime-Guibert (2007) at 30, 60, 90 and 135 days, using the cognitive functioning scale of the EORTC QLQ-C30 (0-100), with higher score indicating higher level of functioning.

Cognitive functioning (30 days)

At 30 days, the mean score for cognitive functioning in the group receiving radiotherapy with supportive care (n= 31) was 59.6 (SD 4.9). The mean score in the group receiving supportive care (n= 28) was 60 (SD 6.1). This resulted in a mean difference of -0.4 (95% CI -3.24 to 2.44). This difference was not clinically relevant.

Cognitive functioning (60 days)

At 60 days, the mean score for cognitive functioning in the group receiving radiotherapy with supportive care (n= 23) was 57.4 (SD 6.7). The mean score in the group receiving supportive care (n= 22) was 63 (SD 5.6). This resulted in a mean difference of -5.6 (95% CI -9.2 to -2). This difference was not clinically relevant.

Cognitive functioning (90 days)

At 90 days, the mean score for cognitive functioning in the group receiving radiotherapy with supportive care (n= 22) was 42.8 (SD 7.1). The mean score in the group receiving supportive care (n= 17) was 63.8 (SD 6.2). This resulted in a mean difference of -21 (95% CI -25.18 to -16.82). This difference was clinically relevant.

Cognitive functioning (135 days)

At 135 days, the mean score for cognitive functioning in the group receiving radiotherapy with supportive care (n= 16) was 43.8 (SD 6.7). The mean score in the group receiving supportive care (n= 10) was 56.8 (SD 7.8). This resulted in a mean difference of -13 (95% CI -18.84 to -7.16). This difference was clinically relevant.

Level of evidence of the literature

1. Survival (critical)

1.1 Progression free survival

The level of evidence regarding the outcome measure progression free survival started as high because it was based on an RCT and was downgraded by two levels to low because of 19/39 participants in the supportive care only group underwent partial- or complete resection of the tumor (-1, bias due to indirectness) and a low number of included patients (n= 81) (-1, imprecision). Because survival is an objective outcome and allocation was centrally performed, the level of evidence was not downgraded for risk of bias.

1.2 Overall survival

RT40 & TMZ: The level of evidence regarding the outcome overall survival started as high because it was based on RCT's and was downgraded by three levels to very low because the confidence interval crosses both boundaries of clinical important difference (-3 imprecision).

RT60: The level of evidence regarding the outcome overall survival was downgraded by three levels to very low because the confidence interval crosses a boundary of clinical important difference (-1 imprecision), heterogeneity (-1, inconsistency) and 19/39 participants in the supportive care only group underwent partial- or complete resection of the tumor (-1, indirectness).

CRT, RT40+BEV-CRT, BEV-CRT: The level of evidence regarding the outcome overall survival was downgraded by three levels to very low because of study limitations (-1, risk of bias) and the confidence interval crosses both boundaries of clinical important difference (-2, imprecision).

2. Quality of life (critical)

The level of evidence regarding the outcome measure quality of life started as high because it was based on an RCT and was downgraded by three levels to very low because of lack of blinding and high attrition rates (-2, risk of bias); and 19/39 participants in the supportive care only group underwent partial- or complete resection of the tumor (-1, bias due to indirectness).

3. Adverse events (critical); 4. Objective response (important)

The level of evidence regarding the outcome measures adverse events and objective response was not graded because of lack of data.

5. Cognitive functioning

The level of evidence regarding the outcome measure cognitive functioning started as high because it was based on an RCT and was downgraded by three levels to very low because of lack of blinding and high attrition rates (-2, risk of bias); and 19/39 participants in the supportive care only group underwent partial- or complete resection of the tumor (-1, bias due to indirectness).

Zoeken en selecteren

The character of the clinical question was broad in order to meet the whole spectrum of potential treatment paths a clinician considers when treating elderly (frail) patients. However, a more focused search question was defined.

A systematic review of the literature was performed to answer the following question: What are the favorable and unfavorable effects of oncologic treatment (i.e. neurosurgery, radiotherapy, systemic therapy (including

chemotherapy) compared to no treatment in elderly (frail) patients with new diagnosed glioblastoma, who qualify for treatment?

Patients: Elderly (frail) patients (over 65 years old) with pathology confirmed glioblastoma who are potentially eligible for treatment

Intervention: Oncological treatment (including neurosurgery (resection/debulking), radiotherapy, chemotherapy, chemoradiation, or systemic therapy)

Control: No treatment after pathology confirmation (best supportive care)

Outcomes: Objective Response, survival (progression-free, or overall), quality of life, cognitive functioning, adverse events.

Relevant outcome measures

The guideline development group considered survival, quality of life and adverse events as a critical outcome measure for decision making; and objective response and cognitive functioning as an important outcome measure for decision making.

A priori, the working group did not define the outcome measures listed above but used the definitions used in the studies.

Per outcome, the working group defined the following differences as a minimal clinically (patient) important differences:

Survival (progression-free, or overall): hazard ratio < 0.7

Quality of life: The minimum important difference (MID) has been estimated to be a difference of 0.08 or more points for the EQ-5D utility index, seven or more points for the EQ-5D VAS (Pickard, 2007), or ≥ 10 points on the Karnofsky Performance Score (KPS).

Cognitive functioning: EORTC cognitive functioning subscale ≥ 10 points.

Adverse events: lethal < 5% (absolute difference), acute or severe < 25%.

Search and select (Methods)

The databases Medline (via OVID) and Embase (via Embase.com) were searched with relevant search terms until December 13nd 2021. The detailed search strategy is depicted under the tab Methods. The systematic literature search resulted in 109 hits. Studies were selected based on the following criteria:

- Systematic reviews (searched in at least two databases, and detailed search strategy, risk of bias assessment and results of individual studies available), randomized controlled trials;
- Full-text English language publication;
- Studies including ≥ 20 (ten in each study arm) patients; and
- Studies according to the PICO

Nineteen studies were initially selected based on title and abstract screening. After reading full texts, one systematic review with network meta-analysis was included (Hanna, 2020).

Results

One study was included in the analysis of the literature. Important study characteristics and results are

summarized in tables (see Table 1). The assessment of the risk of bias is summarized in the risk of bias tables.

Behandeling Gliomatosis cerebri

Uitgangsvraag

Wat is het beleid bij gliomatosis cerebri?

Aanbeveling

Voor een patiënt met gliomatosis cerebri dienen de risico's en de voordelen van de verschillende behandelstrategieën, waaronder chemotherapie en radiotherapie, afgewogen te worden in een multidisciplinaire hersentumorwerkgroep. In de overweging voor de keuze van de primaire behandeling moeten de volgende factoren meegenomen worden: grootte van het gebied van tumorinfiltratie, histologische classificatie en gradering en moleculaire diagnostiek.

De werkgroep is van mening dat voor patiënten met gliomatosis cerebri:

- chirurgische interventie niet geïndiceerd is, behoudens het verrichten van een biopt voor het stellen van de pathologische diagnose. Daarnaast kan in uitzonderlijke gevallen een debulking worden overwogen bij massawerking uitgaande van het tumorproces.
- chemotherapie de eerste keus primaire behandeling is. Gekozen kan worden voor combinatie procarbazine en lomustine of temozolamide.
- radiotherapie kan worden overwogen als eerste en tweedelijnsbehandeling, maar bij de afweging dient rekening te worden gehouden met het aanzienlijke risico op neurotoxiciteit.

Overwegingen

Gliomatosis cerebri is een zeldzame heterogene tumor. De heterogeniteit betreft zowel de histologische classificatie als het klinisch beloop van de ziekte. Dit laatste kan variëren van snel progressief met neurologische uitvalsverschijnselen tot een meer indolent beloop met weinig of geen klinische verschijnselen behoudens epilepsie. Palliatieve therapeutische mogelijkheden zijn vooralsnog chemotherapie of radiotherapie. Gezien de diffuse verspreiding van gliomatosis cerebri (over drie kwabben) zal bij radiotherapie het bestralingsvolume groot zijn, waarbij de kans op vroege en late neurotoxiciteit aanzienlijk wordt geacht. Mede hierdoor wordt bij patiënten met gliomatosis cerebri chemotherapie veelal als primaire behandeling gekozen.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat chemotherapie een effectieve behandeling is voor een deel van de patiënten met gliomatosis cerebri.

Chen 2013⁵³, Rudà 2014²⁸⁴, Glas 2011¹¹²

Er zijn aanwijzingen dat temozolamide even effectief is als de combinatie chemotherapie procarbazine en lomustine / CCNU (PC), maar alleen PC is in prospectieve setting onderzocht.

Glas 2011¹¹², Mattox 2012²¹¹

De resultaten van radiotherapie uit verschillende retrospectieve studies laten onderling grote verschillen zien.

Samenvatting literatuur

Volgens de World Health Organization wordt gliomatosis cerebri gedefinieerd als een diffuus groeiend glioom met uitbreiding in drie of meer hersenkwabben, meestal bilateraal voorkomend en met frequente betrokkenheid van infratentoriële structuren. Gliomatosis cerebri wordt geklassificeerd als een WHO graad III glioom, waarbij radiologische kenmerken worden gecombineerd met histologische kenmerken. De histologische typering en gradering van gliomatosis cerebri door de patholoog is echter zeer variabel. Ofschoon gliomatosis cerebri meestal bestaat uit astrocytaire cellen, kan er ook een oligodendroglial fenotype zijn en is er in een minderheid van de gevallen sprake van glioblastoma multiforme. Er is geen standaardbehandeling voor gliomatosis cerebri. Mede door de zeldzaamheid en de heterogeniteit van deze tumorsoort zijn er geen vergelijkende studies verricht. Behandelkeuzes worden gemaakt aan de hand van één fase II-studie, veelal kleine retrospectieve series, case reports en expert opinions. Zowel bestraling als chemotherapie komen als behandelingsmodaliteit in aanmerking. Heel zelden is er een plaats voor decompressiechirurgie.

In een retrospectieve analyse van 105 patiënten met de diagnose gliomatosis (die tussen 1955 en 1998 werden onderzocht in het MD Anderson Cancer Center), werden 30 patiënten geïdentificeerd van wie follow-up data na bestraling beschikbaar waren [Perkins 2003²⁵⁴]. Binnen deze geselecteerde groep patiënten werd geen verschil in totale overleving (OS) of progressie vrije overleving (PFS) gevonden tussen de groep die alleen een biopsie ondervond en de groep die partiële resectie ondervond. 21/30 patiënten kregen een vorm van chemotherapie verdeeld over 9 regimes en ook hier werd geen verschil waargenomen tussen de wel of niet met chemotherapie behandelde patiënten voor wat betreft PFS en OS. Alle patiënten kregen dus radiotherapie, maar er werd geen verschil gevonden in PFS of OS tussen lokaal, versus whole brain RT (al dan niet in combinatie met chemotherapie).

Chirurgie

Gezien de diffuse verspreiding van de ziekte komen patiënten met gliomatosis cerebri zelden in aanmerking voor chirurgische interventie. Een biopsie wordt verricht voor het stellen van de pathologische diagnose en in geval van ernstige massawerking kan in uitzonderlijke gevallen debulking zinvol zijn. Er zijn geen data beschikbaar die het effect van een operatie ondersteunen.

Radiotherapie

Er zijn alleen retrospectieve data over de effectiviteit van radiotherapie bij patiënten met gliomatosis cerebri op PFS en OS. Bij al deze studies lijkt selectiebias een rol te spelen. De uitkomsten van de diverse studies laten grote verschillen zien. Taillibert analyseerde retrospectief 296 patiënten met gliomatosis cerebri gediagnostiseerd tussen 1993 en 2004, waarbij de OS van patiënten die radiotherapie ondervonden niet verlengd werd in vergelijking met de groep die geen tumorremmende behandeling ondervond [Taillibert 2006³³⁶]. Chen daarentegen beschreef een serie van 54 opeenvolgende patiënten waarbij radiotherapie (als eerste behandeling) sterk geassocieerd was met een betere prognose (PFS 16,5 versus 4,5 mnd., p < 0,01; OS 27,5 vs. 6,5 maanden, p < 0,01) [Chen 2013⁵³]. De studie van Mattox pleit voor combinatie radiotherapie en chemotherapie (temozolamide), gebaseerd op een casus en literatuuronderzoek [Mattox 2012²¹¹].

Chemotherapie

Er is één prospectieve studie betreffende chemotherapie bij gliomatosis cerebri. Glas onderzocht in een fase II-studie de effectiviteit van combinatie chemotherapie procarbazine en lomustine / CCNU (PC) bij 35 onbehandelde patiënten met gliomatosis cerebri [Glas 2011¹¹²]. Het percentage patiënten zonder ziekteprogressie op 8 maanden betrof 50,3%. De mediane progressievrije overleving was 14 maanden (95%CI 6,4-21,6 maanden). De mediane overleving was 30 maanden (95%CI 14,0-45,9 maanden). Sanson beschrijft een retrospectieve serie van 63 patiënten met gliomatosis cerebri die initieel behandeld werden met chemotherapie [Sanson 2004²⁹³]. Zeventien patiënten werden behandeld met combinatie chemotherapie procarbazine, lomustine (CCNU) en vincristine (PCV) en 46 patiënten werden behandeld met monotherapie temozolamide (TMZ). De PFS voor de gehele groep bedroeg 16 maanden en de OS bedroeg 28,8 maanden. Er was geen significant verschil in PFS en OS tussen de met PCV behandelde groep en de met TMZ behandelde groep. Oligodendrogliale tumoren hadden een betere PFS en OS dan astrocytaire en oligoastrocytaire tumoren. In deze studie waren geen data over 1p/19q-status aanwezig. Levin beschreef een serie van 11 patiënten die behandeld werd met TMZ waarbij 45% een objectieve respons optrad en een PFS van 13 maanden werd gerapporteerd [Levin 2004²⁰⁰]. De PFS op 12 maanden was 55%. Louis beschreef in een kleine groep patiënten een zeer goede response na TMZ bij gliomatosis cerebri van het oligodendrogliale subtype [Louis 2003²⁰⁶].

Post-radiatie chemotherapie

Er is één studie die een aanwijzing vond voor voordeel van chemotherapie na radiotherapie [Kong 2010¹⁷⁹]. Binnen deze retrospectieve analyse werd bij 19 patiënten alleen RT gegeven en bij 18 patiënten adjuvante chemotherapie bestaande uit TMZ of lomustine. De mediane overleving voor de patiënten die niet met adjuvante chemotherapie behandeld werden was 13,1 maanden versus 24 maanden voor de patiënten die chemotherapie kregen.

Behandeling Recidief gliomen

De behandeling van recidief gliomen wordt beschreven in de volgende modules:

Systemische therapie

Chemotherapie recidief laaggradig glioom

Chemotherapie recidief anaplastisch glioom

Chemotherapie recidief glioblastoom

Neurochirurgie

Waarde en mate van re-resectie glioblastoom

Radiotherapie

Radiotherapie bij progressie hooggradig glioom/recidief

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Medicamenteuze symptoombestrijding bij gliomen

Deze module is onderverdeeld in de volgende submodules en sub-submodules:

- Corticosteroïden
- Anti-epileptica
 - Rol van anti-epileptica bij de behandeling
 - Invloed van anti-epileptica op de behandeling
- Medicatie in de terminale fase

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Corticosteroïden bij gliomen

Uitgangsvraag

Wat is de rol van corticosteroïden bij de behandeling van patiënten met gliomen?

Aanbeveling

Corticosteroïden zijn effectief in het bestrijden van symptomen ten gevolge van vasogenen oedeem bij met name hooggradige gliomen en vroege complicaties van radiotherapie. Gezien de mogelijke invloed op tumorgroei, betrouwbaarheid van beeldvormend onderzoek, interacties met anti-epileptica en chemotherapeutica en potentieel ernstige bijwerkingen op lange termijn, is de werkgroep van mening dat:

- gestreefd moet worden naar een zo kort mogelijke toediening van corticosteroïden, in een zo laag mogelijke dosering.
- dexamethason als protocollaire medicatie rondom een operatie niet onderzocht is en wellicht achterwege kan blijven, indien dexamethason nog niet gegeven werd.
- dexamethason postoperatief zo snel als op klinische gronden mogelijk is, dient te worden afgebouwd.
- de dosering van corticosteroïden bij klinische verslechtering tijdens radiotherapie tijdelijk verhoogd kan worden; nadien moet opnieuw geprobeerd worden de medicatie af te bouwen.
- gezien de verbeterende overleving, bij langdurig gebruik van corticosteroïden osteoporose-profilaxe overwogen moet worden.

Overwegingen

Hoewel osteoporotische fracturen weinig voorkomen bij gliompatiënten, hebben ze een belangrijke invloed op de kwaliteit van leven. Bij langdurig gebruik (>2,25 mg dexamethason en (verwachte) behandelduur van > 3 maanden) wordt geadviseerd osteoporose profilaxe toe te passen conform de CBO-richtlijn osteoporose. Hoewel het perioperatief gebruik van corticosteroïden in veel klinieken gebruikelijk is voor reduceren van postoperatief oedeem, ontbreekt hiervoor enige wetenschappelijke onderbouwing. In klinieken waar geen corticosteroïden perioperatief worden gegeven per protocol, maar op indicatie voor symptoomreductie, wordt geen toename van postoperatief oedeem waargenomen.

Onderbouwing

Conclusies

Corticosteroïden bestrijden tumor-geassocieerd vasogenen oedeem, met name bij hooggradige gliomen [Dietrich 2011⁸¹]. Het gebruik van corticosteroïden kan gepaard gaan met vele ongewenste bijwerkingen. Er zijn geen vergelijkende studies verricht naar optimale dosering of afbouwschema's.

Samenvatting literatuur

Corticosteroïden verminderen tumor-geassocieerd vasogenen oedeem, hetgeen leidt tot afname van symptomen. Dexamethason is het middel van voorkeur gezien de lange halfwaardetijd en geringe mineralocorticoïde werking [Dietrich 2011⁸¹, Ryan 2012²⁸⁵]. De halfwaardetijd rechtvaardigt een dosering van eenmaal daags.

Er zijn geen wetenschappelijk onderbouwde data met betrekking tot een gestandaardiseerde dosering of afbouwschema's. Aanvangsdoses van 4-16 mg per dag zijn gebruikelijk [Ryan 2012²⁸⁵].

Bij (verdenking op) hooggradige gliomen wordt vaak snel gestart met corticosteroïden. Laaggradige gliomen gaan gepaard met weinig oedeem, de rol van corticosteroïden is initieel meestal beperkt. Rondom een biops of resectie reduceren corticosteroïden het postoperatief oedeem gemeten met beeldvorming, maar klinische uitkomstmaten, zoals postoperatieve complicaties, werden niet onderzocht [Dietrich 2011⁸¹, Kotsarini 2010¹⁸¹, Deutsch 2013⁷⁹]

Corticosteroïden zijn effectief bij de behandeling van vroege complicaties van radiotherapie. Een prospectieve studie naar het gebruik van corticosteroïden tijdens radiotherapie voor hooggradige gliomen, toont dat 87% van de patiënten tijdens radiotherapie behandeld wordt met corticosteroïden. Voor start van radiotherapie was dit 70%. Bij 55% van de patiënten vond tijdens radiotherapie verhoging van de dosis plaats, gemiddeld na 8 dagen. Drie maanden na bestraling was 29% van de patiënten zonder corticosteroïden. Een initiële Karnofsky Performance Score van ≤80 was geassocieerd met een hogere steroïdbehoefte tijdens en na radiotherapie. Een partiële resectie (vs. biops) was geassocieerd met een lagere steroïdbehoefte tijdens, maar niet na radiotherapie [Marantidou 2010²¹⁰].

Er zijn - met name in vitro - aanwijzingen dat corticosteroïden de proliferatie van tumorcellen kunnen remmen of juist stimuleren [Dietrich 2011⁸¹].

Corticosteroïden beïnvloeden de mate waarin contrastvloeistof de bloed-hersenbarrière passeert, hetgeen radiologisch afname van aankleuring kan geven, zonder dat er daadwerkelijk sprake hoeft te zijn van tumorrespons [Dietrich 2011⁸¹, Kotsarini 2010¹⁸¹].

Bij gelijktijdig gebruik van enzym-inducerende anti-epileptica, met name fenytoïne, kan er sprake zijn van interactie: enerzijds kan het effect van dexamethason hierdoor afnemen, anderzijds kunnen de spiegels van anti-epileptica sterker fluctueren. Tevens kan interactie met chemotherapeutica optreden. Er zijn aanwijzingen dat dexamethason cellen kan beschermen tegen temozolamide geïnduceerde apoptose [Dietrich 2011⁸¹]. Bijwerkingen zijn onder andere hyperglycaemie, osteoporose, gewichtstoename, bijnierschors insufficiëntie, myopathie, slapeloosheid, ontremming, psychotische ontregeling, tremor, visusklachten, een verhoogd risico op opportunistische infecties en incidenteel cognitieve stoornissen [Dietrich 2011⁸¹, Ryan 2012²⁸⁵].

Een associatie tussen het gebruik van corticosteroïden en gastro-intestinale bloedingen kon bij retrospectieve analyse van klinische studies niet worden aangetoond. Het standaard voorschrijven van een maagbeschermer is dan ook niet geïndiceerd.

Vanwege het risico op bijwerkingen, dat samen lijkt te hangen met zowel de cumulatieve dosis als behandelduur, moet herhaaldelijk getracht worden de corticosteroïden af te bouwen. Hiervoor bestaan geen standaard schema's. Bij kort gebruik van corticosteroïden (korter dan 10 dagen) is een snelle afbouw gerechtvaardigd, bij langer gebruik moet de dosis langzamer verlaagd worden, met name als fysiologische doseringen bereikt worden om herstel van het adrenerge systeem te bevorderen en het risico op een steroïd onhoudingssyndroom te verkleinen [Ryan 2012²⁸⁵].

Anti-epileptica bij gliomen

Deze submodule is onderverdeeld in de volgende sub-submodules:

- Rol van anti-epileptica bij de behandeling
- Invloed van anti-epileptica op de behandeling

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Rol van anti-epileptica bij de behandeling van gliomen

Uitgangsvraag

Wat is de (profylactische) rol van anti-epileptica bij de behandeling van patiënten met gliomen?

Aanbeveling

Bij patiënten met een glioom zonder epileptische aanvallen dienen geen profylactische anti-epileptica voorgeschreven te worden.

De werkgroep is van mening dat perioperatief profylactisch gebruik van anti-epileptica bij patiënten met een glioom niet gerechtvaardigd is.

De werkgroep is van mening dat bij patiënten met een glioom met epileptische aanvallen gekozen dient te worden voor onderhoudsbehandeling met niet-enzym-inducerende anti-epileptica.

Overwegingen

Er zijn geen studies die het gebruik van een specifiek anti-epilepticum ondersteunen. Het frequent gebruik van comedicatie met potentieel interactie met anti-epileptica door patiënten met een glioom, is een reden om bij voorkeur te kiezen voor niet-enzym-inducerende anti-epileptica.

Onderbouwing

Conclusies

Hoewel epileptische insulten frequent voorkomen bij patiënten met een glioom, zijn er geen gerandomiseerde studies die de keuze voor een bepaald anti-epilepticum ondersteunen.

Het is aannemelijk dat profylactisch gebruik van fenytoïne bij patiënten die niet eerder een insult gehad hebben, niet tot significante risico-reductie leidt, wel tot ongewenste bijwerkingen.

Tremont-Lukats 2008³⁴³

Samenvatting literatuur

Het optreden van epileptische insulten bij patiënten met een glioom kan leiden tot toename van uitvalsverschijnselen en ziekenhuisopname. De incidentie van insulten bij patiënten met een laaggradig glioom varieert tussen 65-85% en bij patiënten met een hooggradig glioom tussen 30-62% in verschillende series [Van Breemen 2007³⁴⁹]

Onderhoudstherapie wordt gestart bij klinisch manifeste insulten. Er zijn geen vergelijkende onderzoeken naar effectiviteit en bijwerkingen van verschillende anti-epileptica bij gliomen [Kerrigan 2011¹⁷⁰]. In kleine studies naar met name het effect van de nieuwere anti-epileptica worden vaak zeer heterogene patiëntengroepen beschreven. Bij de behandeling van epilepsie bij patiënten met een hersentumor hebben anti-epileptica die het cytochrome P450-co-enzymsysteem induceren (carbamazepine, fenobarbital, fenytoïne, oxcarbazepine en topiramaat) niet de voorkeur vanwege de interactie tussen anti-epileptica,

--

chemotherapeutica en andere comedicatie, bijvoorbeeld dexamethason [Brodie 2013³³]. Het ligt daarnaast voor de hand te kiezen voor een eerste-keus middel bij de behandeling van partiële epilepsie [Vecht 2014³⁶³].

Voor een beschrijving van de beschikbare literatuur ten aanzien van individuele anti-epileptica bij neuro-oncologische patiënten wordt verwezen naar de Richtlijn Epilepsie.

De beschikbare literatuur geeft geen ondersteuning voor het profylactisch gebruik van anti-epileptica bij gliomen, terwijl er wel een verhoogd risico bestaat op het optreden van bijwerkingen [Tremont-Lukats 2008³⁴³].

Een prospectieve gerandomiseerde trial naar het gebruik van perioperatieve profylaxe met fenytoïne toont geen significante risico-reductie door het profylactisch gebruik van een adequate dosering fenytoïne in de postoperatieve periode bij patiënten met een supratentoriaal glioom of metastase [Wu 2013³⁹¹]. De algehele incidentie van insulten - ook in de controlegroep - was 8% in de eerste 30 dagen na operatie. De studie bleek van onvoldoende power om een significant verschil tussen de groepen te kunnen aantonen.

Invloed van anti-epileptica op de behandeling van gliomen

Uitgangsvraag

Wat is de invloed van anti-epileptica op de (chemotherapeutische) behandeling?

Aanbeveling

De werkgroep is van mening dat het voorschrijven van enzym-inducerende anti-epileptica als fenytoïne, carbamazepine, oxcarbazepine en topiramaat niet gewenst is bij patiënten die worden behandeld voor een glioom.

De werkgroep is van mening dat er nog onvoldoende data zijn om een behandeladvies te baseren op de aanwijzingen dat het gebruik van valproaat in combinatie met temozolamide de overleving positief zou kunnen beïnvloeden.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat valproaat de overleving van patiënten met een glioblastoom positief zou kunnen beïnvloeden.

Weller 2011³⁸⁰, Simo 2013³¹³, Tsai 2012³⁴⁵, Guthrie 2013¹²¹, Kerkhof 2013¹⁶⁹

Er zijn geen prospectieve gerandomiseerde onderzoeken die de invloed van specifieke anti-epileptica op de chemotherapeutische behandeling beschrijven.

Samenvatting literatuur

Er zijn interacties beschreven tussen anti-epileptica en chemotherapeutica, gebaseerd op het gedeelde cytochrome P450-metabolisme. Enzym-inducerende anti-epileptica als fenobarbital, fenytoïne en carbamazepine geven verlaging van de spiegels van sommige chemotherapeutica en tevens een verhoogd metabolisme van corticosteroïden en verdienen dus niet de voorkeur tijdens chemotherapeutische behandeling [Brodie 2013³³, Oberndorfer 2005²³³].

Valproaat heeft een complexe invloed op de tumorcelproliferatie, waarbij theoretisch zowel stopzetten van de celcyclus als tumorproliferatie kan optreden. Preklinisch onderzoek toont een remmend effect van valproaat aan op DNA-repair mechanismen. Hierdoor kan het cytotoxische effect van chemotherapie of radiotherapie versterkt worden. Er worden *in vitro* geen aanwijzingen gevonden voor een remmend effect van valproaat op het cytotoxisch effect van temozolamide [Chen 2012⁵⁵, Ryu 2012²⁸⁶, Van Nifterik 2012³⁶¹, Berendsen 2012¹⁵].

In een retrospectieve analyse naar het gebruik van anti-epileptica bij patiënten met een glioblastoom die tussen 2000 en 2002 deelnamen aan een studie waarin radiotherapie werd vergeleken met chemoradiotherapie, hadden patiënten in de chemoradiatie-groep die werden behandeld met valproaat monotherapie een significant betere mediane overleving (17 maanden, versus 14 maanden bij patiënten zonder anti-epileptica of alleen enzym inducerende anti-epileptica) [Weller 2011³⁸⁰]. In de groep die alleen behandeld werd met radiotherapie werd geen significant verschil gevonden in overleving. Wel trad bij het

gebruik van valproaat in combinatie met temozolamide vaker trombocytopenie, neutropenie en leukopenie op [Weller 2011³⁸⁰, Simo 2012³¹³].

Ook in andere retrospectieve studies zijn er aanwijzingen dat valproaat de overleving positief zou kunnen beïnvloeden. Er zijn echter geen gerandomiseerde trials die deze bevindingen bevestigen [Tsai 2012³⁴⁵, Guthrie 2013¹²¹, Kerkhof 2013¹⁶⁹].

Medicatie in de terminale fase bij gliomen

Uitgangsvraag

Wat zijn effectieve medicamenteuze interventies om bij een patiënt met een glioom in de terminale fase (met tekenen van intracraniële drukverhoging), de volgende klachten te verminderen:

- hoofdpijnklachten
- onrust
- insulten

Aanbeveling

De werkgroep is van mening dat bij patiënten in de terminale fase:

- hoofdpijnklachten behandeld kunnen worden met een combinatie van corticosteroïden (bij voorkeur eenmaal daags gedoseerd) en opioïden. Als er sprake is van een gedaald bewustzijn kan overwogen worden de toediening van corticosteroïden te staken.
- onrust en agitatie bestreden kunnen worden met neuroleptica en sedativa.
- de behandeling met anti-epileptica zo lang als mogelijk gecontinueerd dient te worden, zo nodig in rectale, buccale, subcutane of intranasale toedieningsvorm. Clonazepam subcutaan (m.b.v. een pompje of in bolussen) sublinguaal of buccaal in doseringen van 2-4 mg per dag lijkt een bruikbaar alternatief als de reguliere anti-epileptica ten gevolge van slikstoornissen niet meer ingenomen kunnen worden.
- het vroegtijdig starten van begeleiding en het geven van voorlichting over het palliatieve traject raadzaam is om de beslissingen ten aanzien van het levenseinde te vergemakkelijken voor zowel patiënt als naasten.

Onderbouwing

Conclusies

Er zijn geen prospectieve gerandomiseerde onderzoeken naar de beste behandeling van de frequent voorkomende symptomen hoofdpijn, onrust en insulten in de terminale fase.

Het is aannemelijk dat corticosteroïden hoofdpijn en symptomen veroorzaakt door oedeem verminderen.
Ryan 2012²⁸⁵

De werkgroep is van mening dat opioïden geschikte analgetica zijn in de terminale fase mede vanwege de mogelijkheid tot subcutane toediening.

De werkgroep is van mening dat onrust en agitatie in de terminale fase bestreden kan worden met neuroleptica of sedativa.

Er zijn aanwijzingen dat een aanzienlijk deel van de patiënten in de laatste week van het leven een epileptisch insult doormaakt, daarom lijkt doorbehandelen met anti-epileptica ook bij dysfagie en bewustzijnsdaling zinvol.

Sizoo 2010³¹⁴, Walbert 2014³⁷²

Het is aannemelijk dat het vroegtijdig starten van begeleiding en het geven van voorlichting over het palliatieve traject de beslissingen ten aanzien van het levens einde kunnen vergemakkelijken en de kwaliteit van leven kunnen vergroten.

Sizoo 2012³¹⁵, Walbert 2014³⁷²

Samenvatting literatuur

Uit enkele retrospectieve studies blijkt dat de meest voorkomende symptomen bij patiënten in de terminale fase bewustzijnsdaling, dysfagie, toenam van focale uitvalsverschijnselen, communicatieve problemen, insulten, incontinentie, hoofdpijn, progressieve cognitieve stoornissen en onrust of verwardheid zijn.

Bewustzijnsdaling en dysfagie gaan vaak samen en treden met name in de laatste week voor overlijden op. Hierdoor wordt de inname van medicatie bemoeilijkt [Sizoo 2010³¹⁴, Walbert 2014³⁷², Sizoo 2014³¹⁶].

Corticosteroïden verminderen klachten van hoofdpijn en de symptomen veroorzaakt door oedeem [Ryan 2012²⁸⁵]. Er zijn geen onderbouwde richtlijnen ten aanzien van de dosering en de behandelduur in de terminale fase. Als het ophogen van de dosis dexamethason niet binnen enkele dagen effectief is, dan is continueren van een hogere dosis niet zinvol en wordt teruggegaan naar de eerdere dosering. Bij slikstoornissen kan dexamethason in gelijke dosering subcutaan worden toegediend. Het continueren van corticosteroïden wanneer inname niet meer mogelijk is door gedaald bewustzijn, lijkt niet zinvol.

Er zijn geen prospectieve studies naar het gebruik van analgetica bij patiënten met een glioom in de terminale fase. Opioïden worden in de terminale fase het meest frequent toegepast en kunnen subcutaan worden toegediend. Terughoudendheid ten aanzien van het gelijktijdig gebruik van corticosteroïden en NSAID's is op zijn plaats vanwege het risico op darmperforaties.

Onrust en agitatie in de terminale fase komen frequent voor bij patiënten met een glioom. Dit wordt behandeld met neuroleptica of sedativa, er zijn geen prospectieve studies naar het effect van deze behandelingen.

Er zijn geen prospectieve studies naar het gebruik van anti-epileptica in de terminale fase. Omdat ruim een derde van de glioompatiënten in de laatste week insulten doormaakt, lijkt het waardevol de behandeling met anti-epileptica ook bij slikstoornissen of bewustzijnsdaling te continueren [Sizoo 2010³¹⁴, Walbert 2014³⁷²]. In de thuissituatie wordt bij voorkeur gekozen voor non-invasieve toediening. Rectale toediening van carbamazepine, levetiracetam, natriumvalproaat en fenobarbital is mogelijk, maar preparaten moeten soms door de apotheker speciaal bereid worden. Clonazepam buccal of sublinguaal is een goed alternatief. Vaak wordt gestart met een dosis van 1-2 mg en een onderhoudsdosering van 2-4 mg per dag. Insulten kunnen gecoupeerd worden met diazepam rectioles, midazolam intranasal of subcutaan of clonazepam buccal.

In de terminale fase zijn patiënten door cognitieve stoornissen, fatische stoornissen of bewustzijnsstoornissen vaak niet meer actief betrokken in de beslissingen rondom het levens einde. Het is aannemelijk dat het vroegtijdig starten van begeleiding en het geven van voorlichting over het palliatieve traject de beslissingen ten aanzien van het levens einde kunnen vergemakkelijken en de kwaliteit van leven kunnen vergroten [Sizoo 2012³¹⁵, Walbert 2014³⁷²].

Cognitie, revalidatie en begeleiding bij gliomen

Deze module is onderverdeeld in de volgende submodules:

- Revalidatie en begeleiding
- Signaleren en behandeling cognitieve en emotionele gevolgen
- Voorlichting
- Rol verpleegkundige/verpleegkundig specialist

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Revalidatie en begeleiding bij gliomen

Uitgangsvraag

Welke vormen van revalidatie en begeleiding zijn effectief om cognitieve klachten, vermoeidheid en stemmingsstoornissen te voorkomen/verminderen bij patiënten met een glioom?

Aanbeveling

Overweeg om patiënten met een laaggradig en anaplastisch glioom een revalidatieprogramma aan te bieden, dat erop is gericht de cognitieve klachten en symptomen te verbeteren.

Onderbouwing

Conclusies

Voor patiënten met een laaggradig en anaplastisch glioom is er bewijs van lage kwaliteit dat direct na het volgen van een revalidatieprogramma de cognitieve klachten verminderen.

Gehring 2009¹⁰⁸

Voor patiënten met een laaggradig en anaplastisch glioom is er bewijs van lage kwaliteit dat zes maanden na het volgen van een revalidatieprogramma de aandacht, verbaal geheugen en vermoeidheid verbeteren.

Gehring 2009¹⁰⁸

Samenvatting literatuur

Ten aanzien van de beantwoording van bovenstaande uitgangsvraag zijn gerandomiseerde gecontroleerde trials (RCT's) of gecontroleerde klinische trials schaars. Een Cochrane review [Khan 2013¹⁷¹] vond op grond van 12 observationele studies 'very low level' evidentiële voor de effectiviteit van een multidisciplinair revalidatieprogramma op de verbetering van de functionele status en kwaliteit van leven van patiënten met primaire hersentumoren. Hoewel recent de effectiviteit van cognitieve revalidatie bij een heterogene groep patiënten (gliomen en meningeomen) met primaire hersentumoren binnen een RCT is aangetoond [Zucchella 2013⁴⁰⁹], evalueerde slechts één RCT de effecten van een revalidatieprogramma op het cognitief functioneren van gliompatiënten [Gehring 2009¹⁰⁸]. Binnen dit onderzoek werden 140 patiënten met een laaggradig of anaplastisch glioom gerandomiseerd in een cognitief revalidatieprogramma of een wachtlijstgroep. De interventie bestond uit een computertraining gericht op herstellen van cognitieve vaardigheden gecombineerd met een face-to-face training gericht op compensatoire vaardigheden voor beperkingen in aandachts-, geheugen- en executieve functies. De compensatietraining bestond uit zes sessies psycho-educatie, met zowel didactische als praktische elementen. Deelnemers kregen een neuropsychologisch onderzoek en vulden vragenlijsten in bij de start van de studie, na voltooiing van de interventie en na 6 maanden.

Direct na de interventie hadden de patiënten in de interventiegroep minder cognitieve klachten dan de patiënten in de controlegroep ($p = 0,001$), maar werd er geen verschil gevonden in cognitieve prestaties. Zes maanden na de interventie waren de aandachtsfuncties en het verbaal geheugen beter in de experimentele groep dan in de controlegroep (respectievelijk $p = 0,004$, $p = 0,009$), maar er werd geen verschil meer gevonden in cognitieve klachten. De interventie had geen significant effect op de kwaliteit van leven, wel

rapporteerden patiënten in de experimentele groep na zes maanden minder vermoeidheidsklachten ($p = 0,044$).

Kwaliteit van het bewijs

Het risico op bias is hoog. Er is vooral een hoog risico op bias door de (onvermijdelijke) afwezigheid van blinding van de patiënten, terwijl de uitkomsten van het vragenlijsonderzoek subjectief zijn. Er is ook geen vermelding van allocation concealment. Hierdoor zijn de effecten van de zelf-gerapporteerde uitkomstmaten weinig betrouwbaar.

Zoeken en selecteren

In de evidence tabellen vindt u de uitkomsten van het literatuuronderzoek voor de vraag: 'Welke vormen van revalidatie en begeleiding zijn effectief om cognitieve klachten, vermoeidheid en stemmingstoornissen te voorkomen/verminderen bij patiënten met een glioom?'

1. Welke diagnostische techniek (MRI, PET, CT perfusie, SPECT) is het beste in staat om bij patiënten met gliomen tumorprogressie en therapie-effect (radionecrose en pseudoprogressie) van elkaar te onderscheiden ten einde een optimale behandelingsstrategie te kunnen kiezen?

P: Patiënten met een glioom die zijn behandeld met radiotherapie waarbij sprake is van een groeiende aankleurende laesie bij wie de differentiaal diagnose tumorprogressie dan wel therapie-effect (radionecrose/pseudoprogressie) is

I: MRI (aankleuring), MRI anatomie, MRI perfusie, MRI diffusie, MRI spectroscopie, PET (MET en FET tracers), CT perfusie, SPECT

C: bevestiging tumorprogressie danwel therapie-effect met PA of klinische follow-up diagnose

O: tumorprogressie of therapie-effect (radionecrose/pseudoprogressie)

Search strategy

Searches were run on October 28, 2013 for systematic reviews and on November 19, 2013 for primary studies. OVID Medline, Embase and the Cochrane Library were searched using a search strings provided in the appendix. The search limits were:

- 2004-2013 for systematic reviews and 2009-2013 for primary studies;
- English and Dutch only;
- At least 30 patients included.

Search results

Systematic reviews

After merging the search files into 1 file and removal of the duplicates, 262 hits were screened on title and abstract. Of these, 245 were excluded. The most important reasons for exclusion were:

1. Other population: patients with other cancer types
2. Other intervention: interventions other than those specified
3. Wrong study design: narrative reviews, observational studies

4. Wrong language: N=32

Of the remaining 17 papers, the full-text was retrieved. Based on the full-text, an additional 12 studies were excluded. Exclusion Table 1 provides an overview of these excluded studies.

Exclusion Table 1. overview of excluded reviews based on full-text evaluation.

PubMed, Embase, PsychInfo en CINAHL were searched. The search strategies can be found in the appendix. Articles published before 2009 and not written in English or Dutch were excluded.

Search results

The PubMed search yielded 209 hits (9-1'14), the Embase search 143 hits (24-1'14), the PsychInfo search yielded 57 hits (23-1'14) and the CINAHL search yielded 18 hits (27-1'14).

Studies were selected if a comparison was made between a control group and an intervention group receiving care to reduce cognitive and emotional functioning and fatigue.

Studies were not selected in case a pharmacological intervention was investigated.

After merging all search files into 1 file (410) and removal of the duplicates, 387 hits were screened on title and abstract. Of these, 375 were excluded. The most important reasons for exclusion were:

- Studies were not on patient with gliomas
- Studies did not make a comparison between interventions

Of the remaining 12 studies the full-text was retrieved. Based on the full-text, an additional 11 studies were excluded. ExclusionTable 4 provides an overview the reason of exclusion of studies.

Exclusion Table 4. overview of excluded studies based on full-text evaluation.

Signalering en behandeling cognitieve en emotionele gevolgen na glioom

Uitgangsvraag

Op welke wijze dienen de cognitieve en emotionele gevolgen van de tumor en/of behandeling te worden gesignaliseerd en behandeld?

Aanbeveling

- Alle gliompatiënten en directe naasten dienen standaard en structureel gescreend te worden op lichamelijke, cognitieve, emotionele en gedragsmatige beperkingen.
- Alle gliompatiënten en directe naasten dienen standaard en structureel gescreend te worden op de behoefte aan psychosociale zorg en zo nodig worden doorverwezen.
- De werkgroep adviseert om bij het in kaart brengen van de gevolgen van de tumor en/of behandeling gebruik te maken van de Signaleringslijst Volwassenen met Niet-Aangeboren Hersenletsel en de Richtlijn Detecteren behoefte psychosociale zorg.
- De werkgroep adviseert om voor het maken van een eerste inschatting van de belasting van de mantelzorger de screeningsvragenlijst 'Ervaren druk door informele zorg' (EDIZ) te gebruiken die is opgenomen in de richtlijn mantelzorg op <http://www.oncoline.nl/>. De werkgroep is van mening dat verwijzen naar een revalidatiearts, psycholoog of klinisch neuropsycholoog zinvol is voor gliompatiënten die hinder ervaren van fysieke en/of cognitieve en emotionele veranderingen waardoor zij beperkt worden in hun dagelijks leven of bij hun maatschappelijke participatie. Voor de behandeling wordt verwezen naar de volgende richtlijnen:
 - Richtlijn Neuropsychiatrische gevolgen van niet-aangeboren hersenletsel
 - Richtlijn Niet-aangeboren Hersenletsel en arbeidsparticipatie
- Er wordt geadviseerd bij de behandeling van vermoeidheidsklachten non-farmacologische interventies toe te passen, zoals deze onder meer beschreven staan in de Richtlijn Vermoeidheid bij kanker.
- Er wordt geadviseerd om bij de behandeling van angststoornissen en depressie gebruik te maken van de multidisciplinaire evidence-based GGZ-richtlijnen voor de diagnostiek en behandeling van patiënten met psychische stoornissen.
- Er wordt geadviseerd bij overbelasting van de informele zorgverleners van hooggradig gliompatiënten, psychologische interventies toe te passen die het mentaal functioneren en gevoelens van controle van informele zorgverleners stabiliseert of verbetert.

Onderbouwing

Conclusies

Cognitieve beperkingen

- Cognitieve revalidatieprogramma's ontwikkeld voor patiënten met niet-aangeboren hersenletsel, lijken ook bruikbaar voor gliompatiënten [Cicerone 2011].
- De werkgroep is van mening dat instrumenten ontwikkeld om veranderingen in emotie, cognitie en gedrag in kaart te brengen bij patiënten met niet-aangeboren hersenletsel, mogelijk ook bruikbaar zijn bij gliompatiënten.
- De werkgroep is van mening dat de verschillende digitaal beschikbare evidence-based

behandelprotocollen voor cognitieve stoornissen bij patiënten met niet-aangeboren hersenletsel, zinvol kunnen zijn voor gliompatiënten.

Cognitieve klachten

- Er is vaak een beperkte samenhang tussen cognitieve klachten en cognitieve beperkingen zoals deze gevonden worden in het neuropsychologisch onderzoek [Aaronson 2011, Boele 2014, Klein 2011].
- Klachten over vermoeidheid en klachten van depressieve aard kunnen cognitieve klachten versterken [Cull 1996].
- De werkgroep is van mening dat instrumenten ontwikkeld om bovengenoemde klachten in kaart te brengen bij patiënten met niet-aangeboren hersenletsel bruikbaar zijn bij gliompatiënten.

Vermoeidheid

- Vermoeidheid is één van de meest voorkomende en meest ingrijpende symptomen bij gliompatiënten [Lovely 1999].
- Farmacologische behandeling van vermoeidheid met modafinil is niet effectiever dan een placebo [Boele 2013²³].

Stemmingsstoornissen

- Van alle oncologische patiënten hebben patiënten met een glioom de grootste kans op psychiatrische symptomen [Rooney 2011²⁸²].
- Er is vaak sprake van een multifactorieel beeld, waarbij bij één patiënt sprake is van zowel depressie als van vermoeidheid en cognitieve beperkingen [Taphoorn 2004³⁴¹].
- De werkgroep is van mening dat verschillende digitaal beschikbare evidence-based behandelprotocollen voor patiënten met psychische stoornissen zinvol kunnen zijn voor gliompatiënten.

Partners

- De begeleiding van en zorg voor gliompatiënten heeft, in vergelijking met de begeleiding van en zorg voor andere kankerpatiënten, door de veranderingen van gedrag en cognitie een grotere invloed op het welbevinden van een informele zorgverlener [Boele 2013²³, Schubart 2008³⁰³].
- Er zijn aanwijzingen dat psychologische interventies het mentaal functioneren en de gevoelens van controle van informele zorgverleners van patiënten met hooggradig gliomen stabiliseren of verbeteren [Boele 2013²³].

Samenvatting literatuur

Cognitieve beperkingen

Gliompatiënten worden geconfronteerd met serieuze bedreigingen voor hun kwaliteit van leven [Liu 2009²⁰³]. De draaglast is hoog en het gevoel van onvermogen is aanzienlijk, vooral bij patiënten met hooggradige gliomen of bij een recidief van de tumor.

Ongeveer 80% van de gliompatiënten heeft cognitieve beperkingen [Giordana 2006¹¹¹]. Deze beperkingen kunnen veroorzaakt worden door de tumor zelf of samenhangen met de medische behandeling, waaronder

radiotherapie, chirurgie, en anti-epileptica [Taphoorn 2004³⁴¹]. De cognitieve beperkingen kunnen veroorzaakt worden door corticale laesies, maar kunnen door de vele corticaal-subcorticale verbindingen ook de oorzaak zijn van subcorticale schade of schade aan cerebellaire structuren. Patiënten met een tumor in de dominante (linker) hemisfeer, hebben vaak meer in het oog springende cognitieve stoornissen dan patiënten met een tumor in de niet-dominante hemisfeer.

Beperkingen komen voor in verschillende cognitieve domeinen, maar voornamelijk in de aandachts- en concentratiefuncties, het geheugen en de executieve functies [Taphoorn 2004³⁴¹]. Hoewel deze beperkingen relatief mild kunnen zijn, kunnen cognitieve beperkingen wel interfereren met het dagelijks leven, zoals werk, sociale- en gezinssituaties.

Relevant voor de screening van gliompatiënten is de [Signaleringslijst Volwassenen met Niet-Aangeboren Hersenletsel](#). Aan de hand van deze vragenlijst, die is ontwikkeld voor patiënten met cerebrale schade die niet veroorzaakt is door hersentumoren, kunnen veranderingen in emotie, cognitie en gedrag in kaart worden gebracht. Deze signaleringslijst kan ook gebruikt worden ter signalering van dergelijke veranderingen bij gliompatiënten. Een geschikt moment voor afname ligt in de subacute fase binnen drie maanden na de diagnose en/of behandeling. Een aanvullend neuropsychologisch onderzoek is zinvol, indien sprake is van een onduidelijk beeld of om onderscheid te maken tussen een depressie en cognitieve problematiek.

Voor wat betreft cognitieve revalidatiemogelijkheden, lijken programma's, die overwegend zijn ontwikkeld voor patiënten met traumatisch hersenletsel en cerebrovasculaire schade, ook bruikbaar te zijn voor neuro-oncologische patiënten [Formica 2011¹⁰²]. Ten aanzien van de mogelijkheden om cognitieve beperkingen te behandelen is het onderzoek van het door [ZonMw](#) gefinancierde consortium Cognitieve Revalidatie relevant. Dit consortium heeft in een aantal onderzoeksprojecten behandelingen van cognitieve stoornissen op effectiviteit geëvalueerd en dit heeft geresulteerd in de [Richtlijn Cognitieve revalidatie bij Niet-Aangeboren Hersenletsel](#). De richtlijnen, ontwikkeld voor verschillende cognitieve stoornissen en gebaseerd zijn op de resultaten van onderzoek van dit consortium, zijn vooral toepasbaar in de settings die hebben deelgenomen aan de effectevaluaties (dit zijn revalidatieafdelingen, zowel binnen de revalidatiecentra als binnen het verpleeghuis en het ziekenhuis). Echter, ook andere settings waar patiënten met niet-aangeboren hersenletsel behandeld worden, kunnen baat hebben bij deze richtlijnen. Verschillende [evidence-based behandelprotocollen](#) zijn digitaal beschikbaar en kunnen worden gedownload. Hierbij is het nadrukkelijk van belang dat de deskundigheid van de zorgverlener van dien aard moet zijn, dat toepassing van de richtlijnen en gebruik van de protocollen verantwoord kan gebeuren.

Cognitieve klachten

De cognitieve klachten die patiënten rapporteren komen vaak niet overeen met de resultaten van het neuropsychologische onderzoek [Janda 2007¹⁵³]. Patiënten met een depressieve stemming kunnen hun cognitieve mogelijkheden onderschatten en de cognitieve klachten die zij uiten zijn vaak een weergave van angstige of depressieve gevoelens of worden veroorzaakt door vermoeidheidsklachten in plaats van cognitieve beperkingen [Hermelink 2010¹³⁴, Taphoorn 2004³⁴¹]. Het hebben van vermoeidheidsklachten en/of een depressie kunnen cognitieve klachten dus versterken.

Om te kunnen beoordelen of verwijzing naar een revalidatiearts, psycholoog of klinisch neuropsycholoog zinvol is voor een individuele patiënt, is het van belang dat de gevolgen van het glioom en/of de behandeling goed in kaart worden gebracht.

In aanvulling op de [Signaleringslijst Volwassenen met Niet-Aangeboren Hersenletsel](#) dienen volgens de [Kwaliteitscriteria neuro-oncologie](#), patiënten standaard gescreend te worden op de behoefte aan

psychosociale zorg en zo nodig te worden doorverwezen. Screening vindt op meerdere ziekte- of behandelingsrelevante momenten in het zorgproces bij voorkeur plaats met de Lastmeter. De patiënt wordt geïnformeerd over de mogelijkheid voor psychosociale ondersteuning in het ziekenhuis of in de eigen omgeving van de patiënt en deze wordt op indicatie en in overleg doorverwezen naar gespecialiseerde aanbieders van psychosociale zorg. De follow-up frequentie wordt bepaald in overleg en op indicatie en is bekend bij patiënt en naasten. De werkwijze en frequentie van de follow-up staan beschreven in het dossier. Bij het inschatten van de aard van de eventuele doorverwijzing kunnen onderstaande richtlijnen met betrekking tot neuropsychiatrische symptomen en gevolgen van hersenletsel voor de arbeidsparticipatie, die verschenen zijn voor patiënten met hersenletsel, ook voor gliompatiënten bruikbaar zijn.

Richtlijn Neuropsychiatrische gevolgen van niet-aangeboren hersenletsel, CBO en Nederlandse Vereniging voor Revalidatieartsen, 2007.

Richtlijn Niet-aangeboren Hersenletsel en arbeidsparticipatie, CBO 2012.

Vermoeidheid

Vermoeidheid is één van de meest voorkomende en meest ingrijpende symptomen bij gliompatiënten [Lovely 1999]. Het is het symptoom met de grootste invloed op de kwaliteit van leven en het dagelijks functioneren van patiënten en hun naasten [Wefel 2008]. Uit resultaten van een kleine studie bleek dat van alle geteste variabelen vermoedheid de sterkste relatie had met kwaliteit van leven bij patiënten met een laaggradig glioom [Gustafsson 2006¹²⁰]. De meest gerapporteerde klachten zijn overmatige slaperigheid, lethargie, concentratieproblemen en onhandigheid [Pelletier 2002²⁵³]. Bij 80% van de gliompatiënten die behandeld worden met radiotherapie is er sprake van vermoedheid. Vermoeidheid blijkt echter ook na behandeling, waarbij geen radiotherapie is gebruikt, te blijven bestaan, naar schatting bij 40% van de gliompatiënten [Struik 2008].

De behandeling van vermoedheid bij gliomen is moeilijk, omdat er nog weinig bekend is over de pathofysiologie en er vaak meerdere factoren tegelijkertijd een rol spelen. De enige dubbelblinde RCT waarbinnen onderzocht werd of een farmacologische behandeling met modafinil beter was dan placebo in de behandeling van vermoedheid, cognitief functioneren en kwaliteit van leven liet zien dat modafinil niet effectiever was dan placebo [Boele 2013²²]. Een wegens moeizame inclusie voortijdig beëindigde open-label RCT [Gehring 2012¹⁰⁷] vond naast inconsistent effecten van methylfenidaat en modafinil op cognitie enige gunstige effecten op zelf-gerapporteerde vermoedheid, stemming en kwaliteit van leven. Voor wat betreft de zelf-gerapporteerde uitkomsten waren er geen verschillen in de tijd tussen de condities.

Gezien het ontbreken van consistent effecten en de beperkte bereidheid van patiënten om medicatie te gebruiken voor vermoedheidsklachten dienen non-farmacologische interventies overwogen te worden.

Binnen de oncologische zorg is de Richtlijn Vermoeidheid bij kanker verschenen. Hierin wordt ook aandacht besteed aan non-farmacologische interventies gericht op onder meer het helpen vinden van een balans tussen inspanning en rust, het aanbieden van fysieke trainingsprogramma's, ontspanningstherapie en psychosociale ondersteuning.

Stemmingsstoornissen

Neuropsychiatrische problemen kunnen ontstaan door het ziekteproces zelf en door de behandeling van neurologische symptomen; zo kan het gebruik van hoge doses corticosteroïden resulteren in restverschijnselen zoals een labiel affect of gedragsveranderingen [Pelletier 2002²⁵³]. De primaire symptomen

van een depressie zijn bij gliompatiënten moeilijk te onderscheiden van de gevolgen van de tumor of de medische behandeling [Rooney 2011²⁸²]. Daadwerkelijke klinische depressie komt echter regelmatig voor wanneer de gezondheidstoestand vermindert. Van alle kankerpatiënten hebben patiënten met een glioom de grootste kans op psychiatrische symptomen, waarbij de prevalentie van depressie bij gliompatiënten wordt geschat op 6-28% [Rooney 2011²⁸²]. De negatieve gemoedstoestand is geassocieerd met de neurologische uitval en wordt versterkt door comorbid psychosociale problemen zoals reactieve depressie, verlies van werk, financiële problemen en echtelijke conflicten [Pelletier 2002²⁵³].

Cognitieve beperkingen en vermoeidheidsklachten kunnen het beroepsmatig- en sociaal functioneren verder beperken en leiden tot gevoelens van frustratie en controleverlies, die een voedingsbodem zijn voor depressieve klachten [Sohlberg 2001]. Een groot deel van de patiënten spreekt hierover niet met zijn of haar behandelend arts, omdat ze deze te druk of onvoldoende toegerust achten om hierin begeleiding te bieden [Wefel 2011³⁷⁶].

Het cognitief functioneren is gecorreleerd met toenemende vermoeidheid en depressie [Liu 2009²⁰³]. Er is dan ook vaak sprake van een multifactorieel beeld, waarbij bij één patiënt sprake is van zowel depressie als van vermoeidheid en cognitieve beperkingen. Bij onderzoek naar specifieke symptoomclusters bij gliompatiënten vormen depressie, vermoeidheid, verstoring van de slaap en cognitieve beperkingen een cluster dat 29% van de variantie van kwaliteit van leven verklaart. Daarnaast vormen depressie, vermoeidheid, verstoring van slaap, cognitieve beperkingen en pijn een cluster dat 62% van de functionele status van de patiënt verklaart [Liu 2009²⁰³].

Bij de behandeling van angststoornissen en depressie kan gebruik worden gemaakt van de multidisciplinaire evidence-based richtlijnen voor de diagnostiek en behandeling van patiënten met psychische stoornissen. Deze richtlijnen zijn ontwikkeld onder auspiciën van de Landelijke Stuurgroep Multidisciplinaire Richtlijnontwikkeling in de GGZ en/of het Trimbos-instituut.

Partners

Net als bij andere ziektes heeft de diagnose van een glioom grote impact op het leven van de patiënt [Gupta 2011¹¹⁹]. Aangezien gliompatiënten naast fysieke symptomen ook worden geconfronteerd met veranderingen in cognitie, stemming en persoonlijkheid hebben zij meer ondersteuning nodig van hun omgeving dan patiënten met een tumor waarbij de hersenen niet zijn betrokken. Inherent aan de problematiek van gliompatiënten is de mogelijkheid dat door de ernst van de cognitieve stoornissen niet de patiënt degene is die de hulpvraag uit, maar zijn omgeving. In de meeste gevallen is de partner de primaire informele zorgverlener [Boele 2013²³]. Het verzorgen van een gliompatiënt heeft, in vergelijking met de verzorging van andere kankerpatiënten, door de veranderingen van gedrag en cognitie een grotere invloed op het welbevinden van een informele zorgverlener [Boele 2013²³, Schubart 2008³⁰³].

Patiënten en hun zorgverleners worden geconfronteerd met de taak de diagnose en behandeling te begrijpen en veranderingen bij de patiënt te identificeren en hiermee om te leren gaan [Gupta 2011¹¹⁹]. Sommige patiënten zullen na behandeling al snel compleet hersteld zijn; er is echter een groot deel van de patiënten dat steun en zorg nodig heeft in de jaren die daarop volgen [Janda 2007¹⁵³]. Deze zorg wordt over het algemeen gegeven door partners en naaste familie. De stress die met de verzorging gepaard gaat, is aanzienlijk en heeft een significant negatieve invloed op het welzijn van de informele zorgverlener zelf [Janda 2007¹⁵³]. Bij 10% van de informele zorgverleners is sprake van een depressieve stemming [Janda 2006¹⁵²] en met name informele zorgverleners van hooggradig gliompatiënten lijken in de acute fase van de ziekte het meeste risico te lopen [Boele 2013²³]. Daarnaast is er sowieso sprake van toenemende symptomen van angst,

psychosomatische problemen, beperkingen van activiteiten, huwelijksproblemen en slechtere fysieke gezondheid bij informele zorgverleners van kankerpatiënten [Weitzner 1999³⁷⁷. Een recente RCT [Boele 2013²³] laat zien dat psychologische interventies het mentaal functioneren en gevoelens van controle van informele zorgverleners van patiënten met hooggradig gliomen kan stabiliseren of verbeteren. Voor het maken van een eerste inschatting van de belasting van de mantelzorger is de screeningsvragenlijst 'Ervaren druk door informele zorg' (EDIZ) ontwikkeld die is opgenomen in de [richtlijn mantelzorg](#) op www.oncoline.nl/.

Voorlichting bij gliomen

Uitgangsvraag

Welke voorlichting dienen de patiënt met gliomen en zijn naasten/omgeving (inclusief huisarts) te ontvangen?

Aanbeveling

De werkgroep is van mening dat de Kwaliteitscriteria neuro-oncologie gevolgd dienen te worden:

- De patiënt ontvangt de PA-diagnose van de hoofdbehandelaar volgens de richtlijn slechtnieuwsgesprek.
- Door de hoofdbehandelaar en/of verpleegkundige/verpleegkundig specialist neuro-oncologie wordt uitleg gegeven over: de ziekte/behandeling, de mogelijke gevolgen hiervan op cognitief, lichamelijk en sociaal gebied en de laatste levensfase.
- In de dialoog tussen hulpverlener en patiënt moeten alle facetten van de mogelijke behandelingsopties, zoals de te verwachten uitkomsten en lasten voor de patiënt, aan de orde komen. Daarnaast is het raadzaam dat de hulpverlener zich op de hoogte stelt van de angsten, visie en prioriteiten van de patiënt.
- De huisarts is op de hoogte van de diagnose en het behandelplan.
- De hoofdbehandelaar draagt zorg voor een schriftelijk overdracht naar de huisarts in alle fasen van het behandelproces. Indien er geen behandeling (meer) aan de patiënt gegeven kan worden en de zorg overgaat op het bestrijden van symptomen in de laatste levensfase, draagt de hoofdbehandelaar de zorg over aan de huisarts.
- Met patiënten worden eventuele alternatieve therapieën besproken. Zorgverleners dienen hier specifiek naar te vragen.
- Mondelinge voorlichting wordt ondersteund door schriftelijk of online voorlichtingsmateriaal (bijvoorbeeld van <http://hersentumor.nl/>).

Overwegingen

Er is geen literatuur beschikbaar van waaruit een uitspraak gedaan kan worden over specifieke behoeften van patiënten met een kwaadaardige hersentumor ten aanzien van communicatie, informatie en begeleiding. De literatuur die vorhanden is niet van recente data. De studies zijn vooral in de Verenigde Staten en Engeland verricht. De laatste tien jaar is er in de Nederlandse ziekenhuizen veel veranderd aan de zorg voor patiënten met hersentumoren. Vrijwel alle academische ziekenhuis en de grote perifere ziekenhuizen in Nederland waar neuro-oncologie een aandachtsgebied is, hebben een gespecialiseerd verpleegkundige/verpleegkundig specialist binnen de keten, die op basis van specifieke deskundigheid betrokken is bij de zorg voor deze complexe patiëntengroep. Daarnaast vervult de verpleegkundige de functie van casemanager en is zij mede verantwoordelijk voor de juiste logistiek in het gehele ziekteproces van de patiënt.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat patiënten vooral behoefte hebben aan gesprekken met arts en gespecialiseerd verpleegkundige waarin aandacht is voor de individuele patiënt en van diens naasten.

Davies 2002⁷¹, Madsen 2011²⁰⁷

Er zijn aanwijzingen dat patiënten behoefte hebben aan zorg op maat, aangepast aan zijn of haar copingstijl.
Davies 1997⁷²

Er zijn aanwijzingen dat naasten van patiënten de zorg voor hun zieke partner met een hersentumor als bijzonder zwaar ervaren. De gedragsverandering die met de ziekte gepaard gaat is hierbij van grote invloed.
Salander 1996²⁸⁹

Er zijn aanwijzingen dat patiënten en naastenbehoefte hebben aan begeleiding in het ziekenhuis van artsen en verpleegkundigen. Tevens zoeken ze steun bij lotgenoten.

Horowitz 1996¹⁴²

Samenvatting literatuur

Het doel van het geven van voorlichting is het informeren van de patiënt en zijn naasten over de diagnose en de gevolgen die dit heeft op het dagelijks leven van zowel de patiënt als zijn omgeving. Deze voorlichting moet opzettelijk en doelbewust gegeven worden. De kennis kan de patiënt en naasten helpen om zelfstandig en bewust, zoveel mogelijk overeenkomstig zijn eigen belang en welzijn, beslissingen te nemen [Van den Ban 1985⁷]. Er is beperkte literatuur beschikbaar waaruit een uitspraak gedaan kan worden over specifieke behoeften van patiënten met een kwaadaardige hersentumor ten aanzien van communicatie, informatie en begeleiding. De beschikbare data zijn verkregen uit observationele studies met kleine aantallen patiënten met een hersentumor. Veelal zijn het ook patiënten met de meest maligne hersentumoren. Deze vooral kwalitatieve studies dateren van (ver) voor 2000 en zijn veelal uitgevoerd in de Verenigde Staten of Engeland. Een systematische review uit 2003 [Davies⁷¹] en uit 2011 [Madsen²⁰⁷] bevat aanwijzingen dat patiënten vooral behoeftte hebben aan gesprekken met een arts en een gespecialiseerd verpleegkundige waarin aandacht is voor de individuele patiënt en van diens naasten. De zorgverleners moeten de tijd nemen voor een zorgvuldig voorbereid gesprek. Patiënten vragen om informatie op maat, aangepast aan de eigen copingstijl [Davies 1997⁷²]. Ten aanzien van de diagnose benoemen patiënten dat de hoop ze niet ontnomen mag worden. Patiënten zijn zich ervan bewust dat de prognose somber is maar dat dit niet steeds benadrukt hoeft te worden. Patiënten zijn kritisch of het ziekenhuis deze ondersteuning wel kan bieden [Davies 1997⁷²].

Patiënten, maar vooral ook naasten, zoeken contact binnen lotgenotengroepen om ervaringen te delen en om te leren omgaan met de zielteklast en met veranderingen binnen het gezin [Leavitt 1996]. Vooral naasten ervaren de zorglast als erg zwaar. De mantelzorgers worden extra belast als de patiënt te maken krijgt met persoonlijkheidsveranderingen. Er ontstaat afstand tussen partners en het verdriet neemt toe [Salander 1996²⁸⁹]. In de lotgenotengroepen wordt door de naasten openlijk gesproken over het omgaan met gedragsveranderingen zonder dat de patiënt hierbij aanwezig is. Ze vinden hierbij duidelijk steun van de lotgenoten [Horowitz 1996¹⁴²].

Een inventarisatie onder patiënten in Nederland beschrijft dat, indien de diagnose hersentumor wordt gesteld, de behandelend arts met de patiënt het behandelplan bespreekt en de vervolgstappen in de behandeling en begeleiding. 'Shared decision making' is hierbij het uitgangspunt [Kwaliteitscriteria cerebraal 2011¹⁸⁹]. In het gehele zorgtraject geven patiënten aan dat ze niet zozeer behoeft te hebben aan standaard

routinecontroles, maar dat de behoefte groter is aan meer individueel gefocuste zorg. Qua medische behandeling heeft een groot deel van de patiënten voldoende aan advies van het multidisciplinaire behandelteam; maar een deel van de patiënten zoekt naar alternatieve genezingen [Verhoef 1999³⁶⁶]. Niet altijd wordt dit met de behandelend arts in het ziekenhuis besproken. Het is niet aangetoond welke wijze van informatie het meest ondersteunend is voor patiënten maar het is aannemelijk dat de spanning van, en tijdens een slechtnieuwsgesprek ertoe bijdraagt dat niet alle informatie wordt opgenomen(zie Richtlijn Handreiking slecht-nieuws gesprek). Het is daarom belangrijk dat de mondelinge informatie ondersteund wordt met schriftelijk informatie. Patiëntenfolders zijn hierbij belangrijk, maar uiteraard ook informatie op het internet, zoals op www.hersentumor.nl. Er is tevens uitgebreide informatie beschikbaar van de diverse ziekenhuizen, maar ook van patiëntenverenigingen. Hiermee kunnen patiënten worden geïnformeerd over de operatie, de bestraling of de behandeling met chemotherapie. Voor lotgenotencontact, informatie en belangenbehartiging kunnen patiënten terecht bij een patiëntenvereniging. Voor patiënten met hersentumoren is dat Vereniging Cerebraal, een patiëntenvereniging voor mensen die getroffen zijn door hersenletsel.

Rol verpleegkundige/verpleegkundig specialist bij gliomen

Uitgangsvraag

Wat is de rol van de verpleegkundige/verpleegkundig specialist bij de behandeling van patiënten met gliomen?

Aanbeveling

De werkgroep is van mening dat de kwaliteitscriteria neuro-oncologie gevolgd dienen te worden:

- Patiënten met een glioom weten wie de inhoudelijk eindverantwoordelijke (hoofdbehandelaar) is, wie het aanspreekpunt en wie de zorgcoördinator is, tijdens alle fasen van de ziekte (diagnose-, behandeltraject, follow-up en palliatieve/ terminale fase).
- Binnen het behandelteam is er een gespecialiseerd verpleegkundige/verpleegkundig specialist neuro-oncologie.
- De verpleegkundige/verpleegkundig specialist neuro-oncologie of de hoofdbehandelaar is het aanspreekpunt voor patiënten en zijn/haar naasten in alle fasen van de ziekte.
- De verpleegkundige/verpleegkundig specialist neuro-oncologie kan vragen van de patiënt over behandeling/ ziekte/problemen adequaat beantwoorden, hetzij op basis van eigen kennis, hetzij door de benodigde informatie bij anderen na te vragen.
- Patiënten ontvangen schriftelijk gegevens over bereikbaarheid van de verpleegkundige/verpleegkundig specialist neuro-oncologie.
- Patiënten weten bij wie ze terecht kunnen met (acute) problemen, binnen en buiten kantooruren.
- De verpleegkundige/verpleegkundig specialist neuro-oncologie heeft structureel een eigen spreekuur op de polikliniek, waar patiënten/naasten terecht kunnen voor advies/informatie aangaande hun ziekte.
- Follow-up frequentie indien medische behandeling afgesloten is, wordt bepaald in overleg met patiënt en naasten.

Overwegingen

In 2012 is het Beroepsprofiel voor de verpleegkundig specialist vastgesteld [Beroepsprofiel verpleegkundig specialist V&V 2020, 2012¹⁶]. Hierin staat nauwkeurig beschreven wat de functie inhoudt en waar de taken uit kunnen bestaan. De inhoud sluit goed aan bij de wensen van patiënten en hun naasten ten aanzien van de zorg en begeleiding in het zorg- en behandelproces. Kernprincipes zijn:

- De verpleegkundig specialist gaat eigen behandelrelaties aan binnen het aandachtsgebied waarin zij deskundig is.
- Vanuit de zorgvraag van de patiënt integreert de verpleegkundig specialist 'cure en care' met als doel de bevordering van de continuïteit en kwaliteit van de verpleegkundige zorg en de medische behandeling, het vermogen tot zelfmanagement van de patiënt en de kwaliteit van leven

Vrijwel alle academische ziekenhuizen en de grote perifere ziekenhuizen in Nederland waar neuro-oncologie een aandachtsgebied is, hebben een gespecialiseerd verpleegkundige/ verpleegkundig specialist binnen de keten die op basis van specifieke deskundigheid betrokken is bij de zorg voor deze complexe patiënten

groep. Daarnaast vervult de verpleegkundige de functie van casemanager en is zij mede verantwoordelijk voor de juiste logistiek in het gehele ziekteproces van de patiënt.

Onderbouwing

Conclusies

Er zijn aanwijzingen dat de gespecialiseerde verpleegkundige zorg een belangrijke rol heeft in de neuro-oncologische keten. De gespecialiseerde verpleegkundige richt zich in de zorg en begeleiding op de patiënt met een hersentumor maar ook op de naasten.

Laurant 2009¹⁹⁴, James 1994¹⁵¹, Leavitt 1996¹⁹⁸, Sardell 2001²⁹⁷, Davies 1996⁷⁰, Spetz 2005³²⁵, Clarke 2003⁶¹

Samenvatting literatuur

Voorlichting en begeleiding over de gevolgen van de ziekte en behandeling is bij uitstek het terrein van een gespecialiseerd verpleegkundige of verpleegkundig specialist met neuro-oncologie als aandachtsgebied. Voor patiënten is het niet noodzakelijk dat alleen de arts de rol van voorlichter op zich neemt. Mits duidelijk is wie welke rol vervuld is hier een grote ruimte voor een gespecialiseerd verpleegkundige [Laurant 2009¹⁹⁴].

Binnen de neuro-oncologie wordt de rol van een gespecialiseerd verpleegkundige aanbevolen [James 1994¹⁵¹, Leavitt 1996¹⁹⁸]. Een telefonisch spreekuur heeft zijn dienst al bewezen [Sardell 2001²⁹⁷].

Mantelzorgers maken ruim twee keer zoveel gebruik van telefonische zorg als patiënten zelf. De vragen betreffen vooral het opnieuw informatie verstrekken, vragen over symptomen van de ziekte, en emotionele ondersteuning [Curren 2001⁶⁶]. De beste de zorg lijkt echter een combinatie van medisch en (gespecialiseerde) verpleegkundige zorg [Davies 1996⁷⁰]. Patiënten en naasten beschrijven de rol van de verpleegkundige als een actief kameraadschap door het gehele ziekteproces. Belangrijke pijlers zijn bereikbaarheid, een proactieve rol, flexibele ondersteuning en professionaliteit en tevens een persoonlijke benadering [Spetz 2005³²⁵, Clarke 2003⁶¹].

Follow-up na gliomen

Deze module is onderverdeeld in de volgende submodules:

- Onderscheiden tumorprogressie en therapie-effect
- Radiologische follow-up tijdens behandeling
- Postoperatieve scan
- Radiologische follow-up na afronden behandeling

Verantwoording

Laatst beoordeeld : 15-04-2015

Laatst geautoriseerd : 15-04-2015

Onderscheiden tumorprogressie en therapie-effect bij gliomen

Uitgangsvraag

Welke diagnostische techniek (MRI, PET, CT perfusie, SPECT) is het beste in staat om bij patiënten met gliomen tumorprogressie en therapie-effect (pseudoprogressie danwel radionecrose) van elkaar te onderscheiden teneinde een optimale behandelingsstrategie te kunnen kiezen?

Aanbeveling

De werkgroep is van mening dat patiënten vervolgd dienen te worden met T1 MRI zonder en met contrast in drie richtingen, aangevuld met T2/FLAIR beeldvorming. Indien hiermee in de follow-up twijfel ontstaat over tumorprogressie of therapie-effect (pseudoprogressie dan wel radionecrose), kan worden overwogen de specificiteit voor het aantonen van tumorprogressie te verhogen middels aanvullende MRI-series (zoals perfusie-MRI-wegingen of spectroscopie), Tc-MIBI-, Thallium-, of GBA-SPECT en of C-MET-, F-DOPA-, of FET-PET. Het beloop in de tijd, beoordeeld middels normale follow-up of eventueel met een vervroegde controle-MRI-scan, kan ook waardevolle informatie verschaffen. Gezien het beperkt beschikbare bewijs, is zowel het vervolgen als de aanvullende diagnostiek een keuze die per patiënt gemaakt kan worden. Bij blijvende twijfel met name bij een symptomatische patiënt valt reoperatie te overwegen voor diagnostiek en eventueel symptoombestrijding.

Overwegingen

Bij een aanzienlijk deel (30-50%) van de patiënten die met radiotherapie, eventueel gecombineerd met chemotherapie, behandeld wordt voor een primaire hersentumor, zal vroeg of laat in het follow-up traject, op beeldvorming onzekerheid optreden of er sprake is van tumorprogressie of therapie-effect (pseudoprogressie dan wel radionecrose) [Taal 2008³³⁴, Brandes 2008²⁸, Fink 2011⁹⁷]. In de literatuur wordt de term pseudoprogressie meestal gereserveerd voor de initiële post-behandeling scans; de term radionecrose wordt vaak later in de follow-up gebruikt. Meestal zal deze twijfel ontstaan door toename in volume van de laesie, nieuwe en/of toegenomen aankleuring zichtbaar na toediening van contrast op de follow-up-MRI binnen het volume van de hersenen dat tot hoge dosis bestraald is. Het huidige literatuuronderzoek laat zien dat een eerste post-behandeling-MRI vaak niet conclusieve beelden laat zien met aankleuring die meer oorzaken kan hebben (sensitiviteit hoog, specificiteit laag). In de praktijk wordt de eerste MRI na behandeling dan ook gebruikt als een uitgangsscan, en wordt een al dan niet versnelde opvolgende MRI scan gebruikt om meer duidelijkheid te verkrijgen. Bij blijvende twijfel staat een scala aan aanvullende technieken, zoals aanvullende MRI-technieken (perfusie, spectroscopie), PET (C-MET-PET, F-DOPA-PET, FET-PET) en SPECT (Tc-MIBI, TI, GBA-SPECT) ter beschikking. Gezien echter de matige kwaliteit van de beschikbare literatuur en de overlap in specificiteit van de verschillende methodes kan geen voorkeur uitgesproken worden voor een daarvan. Een belangrijke overweging in de keuze voor aanvullende beeldvorming is de ervaring met een van deze specifieke onderzoeken binnen het centrum. Ook bij deze aanvullende onderzoeken zal echter enige onzekerheid blijven bestaan over de aard van de progressieve afwijkingen. Men moet zich realiseren dat de kans op pseudoprogressie het grootste is in de eerste drie maanden na de bestraling en afname in de tijd nadien, past derhalve bij pseudoprogressie. Indien twijfel blijft bestaan kan, met name in geval van klinische verschijnselen van de aankleurende laesie, besloten worden tot reoperatie voor een definitieve diagnose en

tevens symptoombestrijding. De a-priori kans op pseudoprogressie/radionecrose, die het grootste is in de eerste drie maanden na de bestraling of chemoradiatie en na hogere bestralingsdoses (>50 Gy), dient te worden meegenomen in deze overweging.

Onderbouwing

Conclusies

Het is aannemelijk dat contrast-enhanced-MR een sensitiviteit van 71-97% en een specificiteit van 24-90% heeft voor de detectie van tumorprogressie (versus radionecrose/pseudoprogressie).

Niveau 2: B Karunanthi 2013¹⁶⁴, Khangembam 2013¹⁷², Santra 2011b²⁹⁵, Santra 2012²⁹⁶, Ozsunar 2010²⁴², Barajas 2009⁸, Chung 2013⁵⁹, Fink 2012⁹⁷, Xu 2010³⁹⁴, Xu 2011³⁹⁵

Het is aannemelijk dat perfusie-MR een sensitiviteit van 88% en een specificiteit van 85% heeft.

Niveau 2: B Deng 2013⁷⁷

Het is aannemelijk dat MR-spectroscopie een sensitiviteit van 64-89% en een specificiteit van 82-89% heeft.

Niveau 2: : B Hollingworth 2006¹³⁹

Er zijn aanwijzingen dat perfusie-CT een sensitiviteit van 82% en een specificiteit van 82-90% heeft.

Niveau 3: B Jain 2011¹⁴⁸

Het is aannemelijk dat Tc-MIBI-SPECT een sensitiviteit van 90% en een specificiteit van 92% heeft.

Niveau 2: B Cheng 2011⁵⁶

Het is aannemelijk dat ²⁰¹Tl-SPECT een sensitiviteit van 40-100% en een specificiteit van 25-100% heeft.

Niveau 2: B Vos 2007³⁷⁰

Er zijn aanwijzingen dat SPECT/CT een sensitiviteit van 86% en een specificiteit van 63% heeft.

Niveau 3: B Karunanthi 2013a¹⁶⁴

Het is aannemelijk dat GHA-SPECT een sensitiviteit van 85-86% en een specificiteit van 97% heeft.

Niveau 2: B Santra 2011a/b^{294 295}

Het is aannemelijk dat C-MET-PET een sensitiviteit van 55-87% en een specificiteit van 70-100% heeft.

Niveau 2: : B Deng 2013⁷⁷, Nihashi 2013²²⁹

Het is aannemelijk dat FDG-PET een sensitiviteit van 77% en een specificiteit van 78% heeft op basis van een meta-analyse [Nihashi] en een sensitiviteit van 81% en een specificiteit van 90% op basis van een bijkomende oorspronkelijke studie [Ozsunar].

Niveau 2: B Nihashi 2013²²⁹, Ozsunar 2010²⁴²

Er zijn aanwijzingen dat FLT/FET-PET een sensitiviteit van 82-91% en een specificiteit van 88-100% heeft.

Niveau 3: B Jeong 2010¹⁵⁸

Het is aannemelijk dat F-DOPA-PET/CT een sensitiviteit van 100% en een specificiteit van 88-89% heeft.

Niveau 2: B Kanunanihi 2013a/b^{164 165}

Er zijn aanwijzingen dat N-ammonia-PET/CT een sensitiviteit van 83% en een specificiteit van 86% heeft.

Niveau 3: B Khangembam 2013¹⁷²

Er zijn aanwijzingen dat C-MET PET/CT een sensitiviteit van 96% en een specificiteit van 88% heeft.

Niveau 3: B Li 2012²⁰²

Het is aannemelijk dat FDG-PET/CT een sensitiviteit van 40-70% en een specificiteit van 97-100% heeft.

Niveau 2: B Li 2012²⁰², Santra 2011a²⁹⁴, Santra 2012²⁹⁶

Bovenstaande conclusies zijn in onderstaande tabel 1 schematisch weergegeven.

Tabel 1. Differentiëren tussen tumorprogressie en therapie-effect

Samenvatting literatuur

We selecteerden vijf systematische reviews, welke in totaal 62 studies includeerden. Bijkomend werden 17 artikelen (16 studies) geselecteerd. Van deze 16 studies is er nog mogelijke overlap tussen de twee studies van Karunanihi en tussen de drie studies van Santra. Het is om die reden onmogelijk het totaal aantal patiënten correct te berekenen, maar uitgaande van de gerapporteerde patiëntenaantallen werden in de oorspronkelijke studies maximaal 831 patiënten ingesloten (mediaan 40, minimum 30, maximum 93). In de volgende studies werden ook patiënten met graad I-gliomen opgenomen: [Karunanihi 2013a¹⁶⁴] (3,7% van de populatie), [Karunanihi 2013b¹⁶⁵] (6%), [Khangembam 2013¹⁷²] (1,9%), [Santra 2011a²⁹⁴] (9%), [Santra 2011b²⁹⁵] (4,8%), [Santra 2012²⁹⁶] (10%).

De studies die in de systematische reviews werden geïncludeerd en de bijkomende oorspronkelijke studies die door ons werden geïdentificeerd hadden allemaal belangrijke methodologische tekortkomingen. Slechts een studie kreeg een A2-niveau van evidence [Chung 2013⁵⁹], alle andere studies kregen een B. De belangrijkste redenen voor dit lage niveau van evidence zijn de kleine patiëntpopulaties en het gebruik van

meerdere referentiestandaarden waarbij in vele gevallen ook de indextest werd gebruikt als referentiestandaard tijdens follow-up (incorporation bias).

MRI (Magnetic Resonance Imaging)

De sensitiviteit van contrast-enhanced-MRI was 92,3-96,7% en de specificiteit 24,1-48,3% in vier studies [Karunanithi 2013b¹⁶⁵, Khangembam 2013¹⁷², Santra 2011b²⁹⁵ en Santra 2012²⁹⁶]. In de studies van Khangembam en Santra werd de accuratesse ook berekend voor subgroepen naar gliomtype. Er werden geen duidelijke verschillen teruggevonden op basis van de 95%-betrouwbaarheidsintervallen. Arterial spin-labeled beelden hadden een sensitiviteit van 88% en een specificiteit van 89%, en dynamic susceptibility contrast-enhanced cerebral bloodvolume beelden een sensitiviteit van 86% en specificiteit van 70% [Ozsunar 2010²⁴²]. Daarnaast kunnen Dynamic Contrast-Enhanced Magnetic Resonance (DCE MR) (T1) perfusie opnames worden gebruikt [Chung 2013⁵⁹].

Vijf studies evalueerden de accuratesse van verschillende afkappunten voor MRI-beelden [Barajas 2009⁸, Chung 2013⁵⁹, Fink 2012⁹⁷, Ozsunar 2010²⁴², Xu 2010³⁹⁴/2011³⁹⁵]. De afwezigheid van 95%-betrouwbaarheidsintervallen of statistische toetsing maakt dat we geen duidelijke uitspraken kunnen doen over eventuele verschillen; de sensitiviteit varieert van 71%-95,7% en de specificiteit van 40%-90,0%. Een bepaald MRI-patroon suggestief voor recurrence (solid enhancement with distinct margins or focally enhancing nodules) had een sensitiviteit van 85% en een specificiteit van 33% [Reddy 2013²⁷⁵]. Tenslotte kwam in een studie alleen subependymale aankleuring naar voren als significant teken van progressie, sensitiviteit was 38,1% en de specificiteit 93,3% [Young 2011⁴⁰⁵].

De systematische review van Deng includeerde zeven studies voor perfusie-MRI en vond een sensitiviteit van 88% en een specificiteit van 85%.

Hollingworth includeerde vier studies voor MRI-spectroscopie en rapporteerde een sensitiviteit tussen 64-89% en een specificiteit tussen 82-89%.

CT (Computed Tomography)

Er was een studie beschikbaar naar de accuratesse van perfusie-CT, met een sensitiviteit van 81,5% en een specificiteit van 81,8-90% voor twee verschillende parameters (rCBV 1,5 en PS 2,5) [Jain 2011¹⁴⁸].

SPECT (Single-Photon Emission Computed Tomography)

De diagnostische accuratesse van SPECT werd gerapporteerd in twee systematische reviews [Cheng 2011⁵⁶, Vos 2007³⁷⁰] en in drie oorspronkelijke studies [Karunanithi 2013a¹⁶⁴, Santra 2011a²⁹⁴, Santra 2011b²⁹⁵].

De sensitiviteit en specificiteit van Tc-MIBI-SPECT (Technetium Methoxyisobutylisonitrile SPECT) was respectievelijk 89,8% en 91,9% op basis van een meta-analyse van zes studies [Cheng 2011⁵⁶].

De systematische review van Vos voerde geen meta-analyse uit omwille van de belangrijke heterogeniteit, en rapporteerde voor ²⁰¹Tl (Thallium)-SPECT een sensitiviteit tussen 43-100% en een specificiteit tussen 25-100%.

Een primaire prospectieve studie vond voor SPECT-CT een sensitiviteit van 86,4% en een specificiteit van 62,5% [Karunanithi 2013a¹⁶⁴]. Het hanteren van verschillende afkapwaarden resulteerde in lagere sensitiviteit en hogere specificiteit: T/S (tumour/striatum) ratio van 0,83 sensitiviteit 75%, specificiteit 86%; T/NP (tumour/nasopharynx) ratio 0,2 sensitiviteit 50%, specificiteit 95%.

Tenslotte werd GHA (glucoheptonate)-SPECT geëvalueerd in twee studies met een sterk vermoeden van gedeeltelijke overlap in de patiëntenpopulatie [Santra 2011a²⁹⁴, Santra 2011b²⁹⁵]. In deze studies werd een

sensitiviteit van 84,7%-86,5% en specificiteit van 96,8-96,5% gerapporteerd.

PET (Positron Emission Tomography)

Er waren twee systematische reviews met resultaten over PET [Deng 2013⁷⁷, Nihashi 2013²²⁹]. Deng vond voor C-MET (Methionine)-PET een gepoolde sensitiviteit en specificiteit van 87% en 81,3% op basis van elf studies, Nihashi heeft voor C-MET-PET geen meta-analyse uitgevoerd en vond een sensitiviteit van 55-80% en een specificiteit van 70-100% op basis van zeven studies. Voor enkel hooggradige gliomen leek de sensitiviteit iets hoger (70%).

Nihashi vond voor FDG-PET een gepoolde sensitiviteit van 77% en een gepoolde specificiteit van 78%, met vergelijkbare accuratesse bij enkel hooggradige gliomen. Bijkomend werd voor FDG-PET een sensitiviteit van 81% en een specificiteit van 90% gevonden in een primaire diagnostische studie [Ozsunar 2010²⁴²].

FLT/FET-PET werd gerapporteerd in een oorspronkelijke studie [Jeong 2010¹⁵⁸] voor verschillende afkapwaarden, variërend met een sensitiviteit van 81,8-91,3% en een specificiteit van 87,5-100%.

PET/CT

Twee studies evalueerden F-DOPA (Fluorodopa) PET/CT [Karunanithi 2013a¹⁶⁴, Karunanithi 2013b¹⁶⁵], waarbij er mogelijke een overlap is tussen deze studies. De sensitiviteit was 100% in beide studies, de specificiteit 87,5% en 88,9% respectievelijk. In de eerste studie werden ook nog verschillende afkappunten geanalyseerd, resulterend in een onveranderde sensitiviteit (87,5%) en een specificiteit variërend tussen 95,4-100%.

N-ammonia-PET/CT had in een studie een sensitiviteit van 82,6% en een specificiteit van 86,2%; verschillende afkapwaarden resulteerden in een sensitiviteit variërend tussen 65,2-73,9% en een specificiteit tussen 82,8-89,7% [Khangembam 2013¹⁷²].

Er was een oorspronkelijke studie voor C-MET-PET/CT welke een sensitiviteit van 96,4% en een specificiteit van 87,5% rapporteerde [Li 2012²⁰²].

Voor FDG (Fludeoxyglucose)-PET/CT waren drie studies beschikbaar [Li 2012²⁰², Santra 2011a²⁹⁴, Santra 2012²⁹⁶], maar deze twee rapporteren identieke resultaten en zijn vermoedelijk gebaseerd op dezelfde patiënten [Santra 2011a, Santra 2012]. Hierdoor zijn er slechts twee in plaats van drie sets van resultaten beschikbaar: de sensitiviteit is 46,4% en 69,5%, de specificiteit is 100% en 96,8%.

Radiologische follow-up tijdens behandeling bij het glioblastoom

Uitgangsvraag

Met welke frequentie dient radiologische follow-up plaats te vinden tijdens behandeling bij het glioblastoom?

Aanbeveling

De werkgroep is van mening dat, zeker indien een (experimentele) vervolgbehandeling tot de mogelijkheden behoort, MRI-beeldvorming op gezette tijden de meest voor de hand liggende strategie is. In overleg met de patiënt kan hier van worden afgezien en op klinische indicatie beeldvorming worden verricht.

Overwegingen

Omdat MRI-beeldvorming tijdens chemoradiotherapie behandeling verwarringende uitkomsten kan opleveren, zal voorafgaand aan het verrichten van deze beeldvorming het doel en de consequentie hiervan bij de behandelaren alsmede de patiënt en diens naasten duidelijk moeten zijn. Een MRI-scan met moeilijk te interpreteren beelden kan onrust veroorzaken bij patiënt en familie. Echter, wanneer de eerste scan pas na de zesde adjuvante kuur gemaakt wordt, worden patiënten potentieel langer dan nodig blootgesteld aan ineffectieve chemotherapie.

Steeds zal de onrust, veroorzaakt door een potentieel moeilijk interpreteerbare MRI kort na de bestraling, moeten worden afgewogen tegen het voordeel van op een vroeger tijdstip vaststellen van een recidief met potentieel een betere uitgangssituatie voor (experimentele) vervolgbehandeling evenals het tijdig staken van ineffectieve chemotherapie.

Onderbouwing

Conclusies

De werkgroep is van mening dat er geen bewijs is voor een specifieke strategie ten aanzien van het maken van vervolgsans tijdens gecombineerde chemoradiatiabehandeling, maar dat de enige onderzochte strategie MRI-beeldvorming is vier weken na (chemo-)radiotherapie en na de derde en zesde adjuvante kuur. Stupp 2005³³²

Samenvatting literatuur

De direct postoperatieve MRI wordt in de module Postoperatieve scan besproken. In deze module zal alleen worden ingegaan op de MRI-beeldvorming tijdens chemo-radiotherapie behandeling. Er zijn geen publicaties gevonden waarin de invloed van het moment en de frequentie van MRI-beeldvorming tijdens de behandeling op het ziektebeloop of de prognose wordt onderzocht.

In de oorspronkelijke studie waarin de toegevoegde waarde van gelijktijdig en adjuvant temozolomide chemotherapie bij het glioblastoom werd aangetoond, EORTC-studie-26981, werd MRI-beeldvorming verricht vier weken na de radiotherapie, evenals na de derde en na de zesde adjuvante kuur [Stupp 2005³³¹]. Een MRI met name in de eerste drie maanden na de (chemo)radiotherapie levert vaak moeilijk interpreteerbare beelden op met 20-30% pseudoprogressie als gevolg van de behandeling [Wen 2010³⁸², Van den Bent 2011³⁵⁹, Vogelbaum 2012³⁶⁸]. Zie ook de evidence based module Onderscheiden tumorprogressie.

en therapie-effect. Deze pseudoprogressie is zichtbaar als aankleuring op een T1-gewogen opname na contrast en is moeilijk met zekerheid te onderscheiden van werkelijke tumorprogressie. Alleen wanneer er binnen de eerste drie maanden na bestraling een nieuwe aankleurende laesie is *buiten* het bestralingsveld kan met zekerheid gesteld worden dat er sprake is van progressie. Het doel van de MRI vier weken na de radiotherapie is dan ook voornamelijk om een uitgangswaarde te hebben waarmee vervolgscans kunnen worden vergeleken. Een andere mogelijkheid is om de eerste MRI na de chemoradiotherapie behandeling pas laat te maken bijvoorbeeld na drie adjuvante kuren of zelfs na beëindiging van de gehele behandeling. Het risico van deze strategie is dat een recidief pas wordt vastgesteld wanneer klinische achteruitgang is opgetreden met verslechtering van de conditie en daarmee een slechtere uitgangssituatie voor (experimentele) vervolgbehandeling. Net als bij het nieuw gediagnosteerd glioom is ook bij patiënten met een recidief glioom een slechtere performancestatus bij aanvang van de recidiefbehandeling een prognostisch ongunstige factor [Wong 1999³⁹⁰, Park 2010²⁴⁹].

Postoperatieve scan bij gliomen

Uitgangsvraag

Wat is het moment waarop de eerste postoperatieve scan moet worden gemaakt bij patiënten met een laaggradig/anaplastisch/glioblastoom?

Aanbeveling

De werkgroep is van mening dat een vroege postoperatieve MRI (<72uur) voor zowel laag- als hooggradige tumoren zinvol kan zijn. Er is echter geen bewijs dat het weglaten van deze vroege postoperatieve MRI nadelige prognostische consequenties heeft. Daarom is het wel of niet maken van een direct postoperatieve MRI een keuze die in samenspraak tussen de verschillende behandelaars gemaakt dient te worden.

Onderbouwing

Conclusies

Het is aannemelijk dat op een vroege postoperatieve MRI-scan de mate van tumorresectie kan worden vastgesteld bij aankleurende gliomen.

Van den Bent 2013³⁵⁴, Cairncross 2013⁴¹, Zaidi 2014⁴⁰⁸, Smets 2013³¹⁸, Albert 1994⁴, Ekinci 2003⁹⁰

Het is aannemelijk dat een vroege postoperatieve MRI-scan als uitgangsscan kan dienen voor verdere follow-up MRI's bij aankleurende gliomen.

Van den Bent 2013³⁵⁴, Cairncross 2013⁴¹, Zaidi 2014⁴⁰⁸, Smets 2013³¹⁸, Albert 1994⁴, Ekinci 2003⁹⁰

Er zijn aanwijzingen dat een vroege postoperatieve MRI het meest betrouwbaar is zo vroeg mogelijk na de operatie en in ieder geval binnen 72 uur.

Zaidi 2014⁴⁰⁸, Smets 2013³¹⁸, Albert 1994⁴, Ekinci 2003⁹⁰

Het is niet bekend of het wel of niet maken van een direct postoperatieve MRI tot verschillen leidt in behandeling en/of overleving.

Zaidi 2014⁴⁰⁸, Smets 2013³¹⁸, Albert 1994⁴, Ekinci 2003⁹⁰

Samenvatting literatuur

In de RANO-richtlijnen [Wen 2010³⁸², Van den Bent 2011³⁵⁹, Vogelbaum 2012³⁶⁸] wordt aangeraden de eerste postoperatieve scan bij laag- en hooggradige gliomen zo vroeg mogelijk en in ieder geval binnen 72 uur na de operatie te maken om resttumor en operatie-effecten zoals ischemie (zichtbaar als diffusierestrictie) en contusie vast te kunnen stellen. Als de MRI-scan later wordt gemaakt kunnen postoperatieve effecten zorgen voor aankleuring op T1-gewogen MRI-opnames na contrast die niet te onderscheiden is van rest- of recidiettumor [Cairncross 2013⁴¹, Zaidi 2014⁴⁰⁸]. Voor glioblastoom en anaplastisch glioom (met aankleuring) kan deze MRI tevens dienen als uitgangs-MRI voor de mate van resttumor. Bij laaggradige tumoren en anaplastisch glioom zonder aankleuring is het volgens de RANO-richtlijn raadzaam de uitgangs-MRI voor T2-gewogen beelden later dan twaalf weken na de operatie plaats te laten vinden [Wen 2010³⁸², Van den Bent 2011³⁵⁹, Vogelbaum 2012³⁶⁸]. Bij een eerdere MRI-scan kan er nog postoperatief oedeem aanwezig zijn die

niet te onderscheiden is van resttumor. Echter ook voor laaggradige tumoren kan worden overwogen om een vroege MRI te maken korter dan 72 uur na de operatie. Het eventuele effect van een vroege postoperatieve MRI op behandelkeuzes en patiënten-uitkomstmaten is niet bekend. Voor de interpretatie van veranderingen op MRI bij verdere follow-up met MRI-beeldvorming is de uitgangs-MRI-scan wel van belang.

Gezien de rol van de (rest)aankleuring bij de afweging om een MRI-scan vroeg (<48-72uur) of laat (>12 weken) na de operatie te maken zal bij hooggradige gliomen het moment van de MRI-scan afhangen van de wel/niet aanwezige aankleuring. Als er aankleuring aanwezig is, lijkt het het meest logisch om ook bij deze hooggradige gliomen de postoperatieve MRI binnen 48-72uur na de operatie te maken [Van den Bent 2013³⁵⁴, Cairncross 2013⁴¹]. Er is discussie over de waarde van deze direct postoperatieve MRI omdat er ook al vroeg aankleuring aanwezig kan zijn, bijvoorbeeld door operatieve manipulatie en bloed-hersenbarrière verstoring [Zaidi 2014⁴⁰⁸]. Wel is de aanwezigheid van aankleuring op een vroege postoperatieve scan een prognostische factor [Smets 2013³¹⁸, Albert 1994⁴, Ekinci 2003⁹⁰]. Er zijn geen vergelijkende studies gedaan waarbij de prognostische waarde is vergeleken tussen de vaak gehanteerde <48uur of <72uur postoperatieve MRI's [Albert 1994⁴, Ekinci 2003⁹⁰].

Radiologische follow-up na afronden behandeling bij glioblastoom

Uitgangsvraag

Met welke frequentie dient radiologische follow-up plaats te vinden na afronden van de behandeling bij het laaggradig/anaplastisch/glioblastoom?

Aanbeveling

De werkgroep is van mening dat radiologische follow-up bij patiënten met een glioom alleen moet worden verricht wanneer er klinische en/of therapeutische consequenties zijn.

Het doel van radiologische follow-up is het in een vroeg stadium opsporen van tumorgroei en daarmee de mogelijkheid voor en de slagingskans van vervolgbehandeling al dan niet in studieverband te optimaliseren.

De werkgroep is van mening dat de volgende radiologische follow-up frequentie gehanteerd kan worden:

- patiënten met een glioblastoom (WHO graad IV): drie tot zes maanden
- patiënten met een anaplastisch glioom (WHO graad III): drie tot zes maanden
- patiënten met een laaggradig glioom (WHO graad II): zes tot twaalf maanden

De werkgroep is van mening dat mede gezien het ontbreken van wetenschappelijk bewijs, tumorfactoren en patiëntgerelateerde factoren een rol spelen in het komen tot een optimale follow-up frequentie voor de individuele patiënt binnen de hierboven genoemde grenzen.

Overwegingen

De optimale radiologische follow-up frequentie bij patiënten met een laag- of hooggradig glioom zal van verschillende factoren afhankelijk zijn. Bij het ontbreken van vergelijkende studies of series in de literatuur zullen klinische en/of patiëntgerelateerde argumenten een grote rol spelen. Zo kan grootte en lokatie van (rest)tumor belangrijk zijn en kan ook de wens van de patiënt meegewogen worden. Daarnaast kan kosteneffectiviteit een argument zijn in de besluitvorming over follow-up frequentie.

Geplande follow-up zal in het algemeen alleen plaatsvinden als er behandelbaarheden of klinische consequenties bestaan bij aantonen van recidief tumor, tumorgroei of radiologische kenmerken van dedifferentiatie naar hogere gradering. Het doel van de follow-up is om voorgenomen events in een vroeg stadium op te sporen, vóór de patiënt (ernstige) neurologische uitvalsverschijnselen vertoont. De mogelijkheid voor en de slagingskans van een vervolgbehandeling of behandeling in studieverband is namelijk sterk afhankelijk van de performance status van de patiënt.

In hoeverre de hoge follow-up frequentie in de studies van Stupp en Van den Bent daadwerkelijk heeft bijgedragen aan de overlevingswinst van respectievelijk patiënten met een glioblastoom en een AO is niet duidelijk. Het vroeg opsporen van recidiettumor of tumorgroei heeft mogelijk wel geleid tot het eerder of vaker starten van een vervolgbehandeling.

Onderbouwing

Conclusies

De werkgroep is van mening dat op basis van de literatuur geen uitspraak kan worden gedaan over de optimale frequentie van radiologische follow-up voor patiënten met hoog- en laaggradige gliomen. In een aantal klinische trials is de methode en frequentie van follow-up duidelijk beschreven [Stupp 2005³³¹, Van den Bent 2013³⁵⁴]. In de overige trials is de frequentie van follow-up variabel óf niet beschreven.

Samenvatting literatuur

Er zijn voor zowel laag- als hooggradige gliomen geen studies waarin verschillende frequenties van radiologische follow-up worden vergeleken.

In de studie van Stupp [Stupp 2005³³¹], die de standaardbehandeling van het glioblastoom herdefinieerde, werd een follow-up frequentie van drie maanden aangehouden. Twee trials bij anaplastische oligodendrogliomen [Van den Bent 2013³⁵¹, Cairncross 2013⁴¹] hanteerden verschillende follow-up frequenties. In de studie van Van den Bent werd elke drie maanden een MRI of CT verricht. In de studie van Cairncross wordt geen precieze follow-up frequentie genoemd, maar beschreven als variabel en oplopend qua interval, naarmate de overleving langer werd. Na vijf jaar werd een MRI of CT jaarlijks gemaakt of alleen 'wanneer nodig'. Bij deze twee studies waren de progressie vrije overleving (PFS) en de totale overleving (OS) vergelijkbaar. Wick onderzocht bij patiënten met een anaplastische astrocytoom de volgorde van behandeling (radiotherapie gevolgd door chemotherapie en andersom) daarbij werd de frequentie en methode van follow-up niet beschreven [Wick 2009³⁸⁶, Wick 2012³⁸⁷]. Bij laaggradige tumoren is in studies en beschreven series de gehanteerde follow-up frequentie variabel (zes tot twaalf maanden) óf niet gerapporteerd.
